91 Data and Assessment

data-and-assessment

92 California scorpionfish was assessed in 2005 (Maunder et al. [2005](#)) using Stock Synthesis
93 II version 1.18. This assessment uses the newest version of Stock Synthesis (3.30.0.4). The
94 model begins in 1916, and assumes the stock was at an unfished equilibrium that year.

95 Map of assessment region: (Figure [e](#)).

¹⁰⁶ **Exploitation status**

`exploitation-status`

¹⁰⁷ Exploitation Tables: Table [d](#) Exploitation Figure: Figure [i](#)).

¹⁰⁸ A summary of California scorpionfish exploitation histories for base model is provided as
¹⁰⁹ Figure .

Table d: Recent trend in spawning potential ratio and exploitation for California scorpionfish in the base model. Fishing intensity is (1-SPR) divided by 50% (the SPR target) and exploitation is F divided by F_{SPR} .

Year	Fishing intensity	~ 95% confidence interval	Exploitation rate	~ 95% confidence interval
2007	0.53	(0.29-0.78)	0.08	(0.04-0.11)
2008	0.46	(0.23-0.69)	0.06	(0.03-0.09)
2009	0.50	(0.26-0.75)	0.07	(0.04-0.1)
2010	0.49	(0.26-0.73)	0.07	(0.04-0.1)
2011	0.51	(0.27-0.75)	0.07	(0.04-0.1)
2012	0.57	(0.32-0.83)	0.08	(0.05-0.12)
2013	0.58	(0.32-0.84)	0.09	(0.05-0.13)
2014	0.64	(0.37-0.91)	0.10	(0.05-0.14)
2015	0.53	(0.28-0.78)	0.07	(0.03-0.1)
2016	0.50	(0.26-0.74)	0.05	(0.02-0.08)

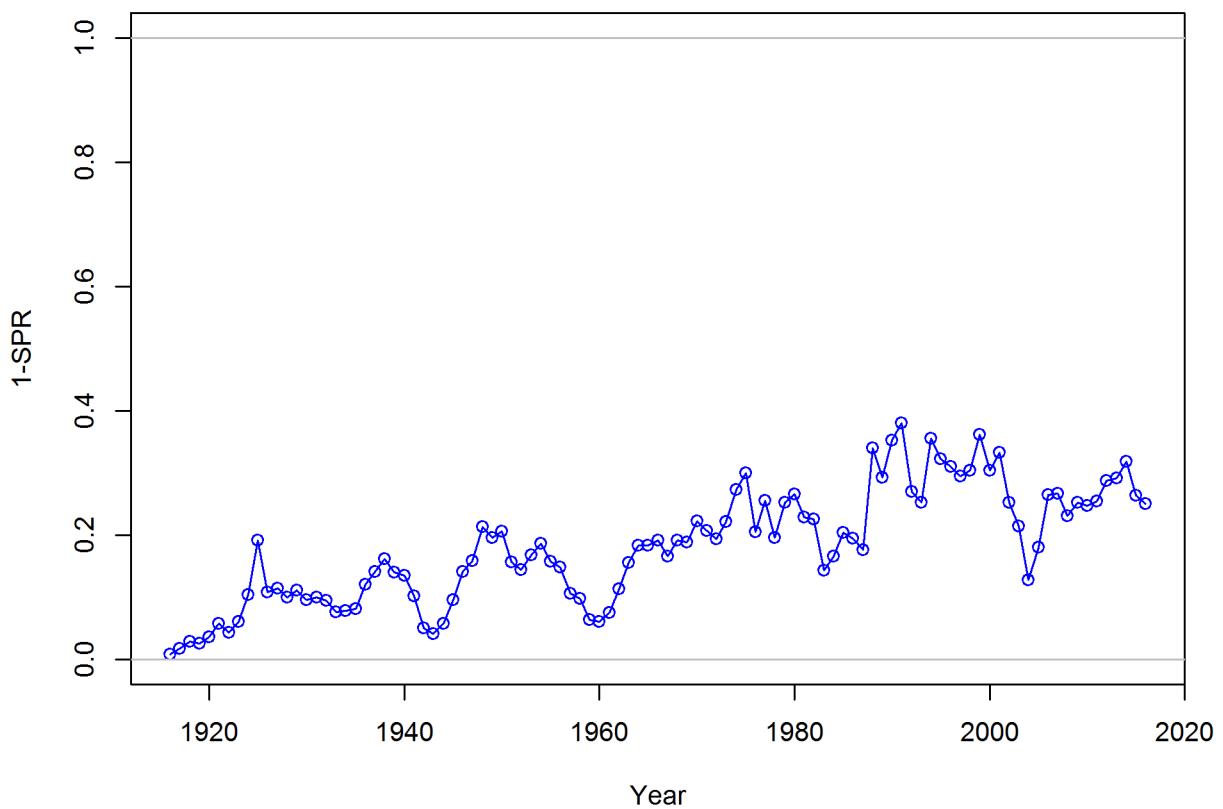

Figure i: Estimated spawning potential ratio (SPR) for the base-case model. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis. The management target is plotted as a red horizontal line and values above this reflect harvests in excess of the overfishing proxy based on the $\text{SPR}_{50\%}$ harvest rate. The last year in the time series is 2016. | [fig:SPR_all](#)

110 **Ecosystem Considerations**

ecosystem-considerations

111 In this assessment, ecosystem considerations were. . . .

112 **Reference Points**

reference-points

113 This stock assessment estimates that California scorpionfish in the base model are above the
114 biomass target, but above the minimum stock size threshold. Add sentence about spawning
115 output trend. The estimated relative depletion level for Model 1 in 2016 is 55.6% (~95%
116 asymptotic interval: ± 40.5%-70.7%, corresponding to an unfished spawning output of 493.509
117 mt (~95% asymptotic interval: 242.88-744.14 mt) of spawning output in the base model
118 (Table e). Unfished age 1+ biomass was estimated to be 2218.6 mt in the base case model.
119 The target spawning output based on the biomass target ($SB_{40\%}$) is 355.2 mt, which gives
120 a catch of 218.4 mt. Equilibrium yield at the proxy F_{MSY} harvest rate corresponding to
121 $SPR_{50\%}$ is 205.4 mt.

Table e: Summary of reference points and management quantities for the base case base model.

Quantity	Estimate	tab:Ref_pts_mod1 95% Confidence Interval
Unfished spawning output (mt)	888	(617.9-1158.1)
Unfished age 1+ biomass (mt)	2218.6	(1480.3-2956.8)
Unfished recruitment (R0, thousands)	3305.4	(1266.9-5343.9)
Spawning output(2016 mt)	431.6	(218.8-644.3)
Depletion (2016)	0.486	(0.3659-0.6062)

¹³⁴ **Rebuilding Projections**

rebuilding-projections

₁₃₅ **1 Introduction**

introduction

₁₃₆ **1.1 Basic Information and Life History**

basic-information-and-life-history

₁₃₇ California scorpionfish (*Scorpaena guttata*), also known locally as sculpin or spotted scorpionfish, originates from the Greek word for scorpionfishes and *guttata* is Latin for speckled.
₁₃₈ California scorpionfish is a medium-bodied fish and like other species in the genus *Scorpaena*,
₁₃₉ it produces a toxin in its dorsal, anal, and pectoral fin spines, which produces intense, painful
₁₄₀ wounds (Love et al. 1987). Scorpionfish are very resistant to hooking mortality and have
₁₄₁ shown survival under extreme conditions.

₁₄₃ Its range extends from central California (Santa Cruz) to the Gulf of California, although
₁₄₄ within U.S. waters they are most common in the Southern California Bight (Eschmeyer et al.
₁₄₅ 1983, Love et al. 1987). The species generally inhabits rocky reefs, caves and crevices, but in
₁₄₆ certain areas and seasons it aggregates over sandy or muddy substrate (Frey 1971, Love et
₁₄₇ al. 1987). California scorpionfish have been observed from the intertidal to 600 ft with a
₁₄₈ preferred depth range from 20-450 ft.

₁₄₉ Males and females show different growth rates, with females growing to a larger size than
₁₅₀ males, and the sexes exhibit different length-weight relationships (Love et al. 1987). Few
₁₅₁ California scorpionfish are mature at one year old (14 cm total length). Fifty-percent of fish
₁₅₂ mature at 17-18 cm (2 years old) and all by 22 cm (4 years old) (Love et al. 1987).

₁₅₃ California scorpionfish feed on a wide variety of mobile prey, including crabs, fishes (e.g.,
₁₅₄ include northern anchovy, spotted cusk-eel), octopi, isopods and shrimp, (Taylor 1963, Quast
₁₅₅ 1968, Turner et al. 1969, Love et al. 1987). The species is nocturnal, but have been observed
₁₅₆ feeding during the day. Predation on scorpionfish is believed to be low, but one individual
₁₅₇ was found in the gut of a leopard shark (Love pers comm.).

₁₅₈ **1.2 Early Life History**

early-life-history

₁₅₉ California scorpionfish utilize the “explosive breeding assemblage” reproductive mode in
₁₆₀ which fish migrate to, and aggregate at traditional spawning sites for brief periods (Love
₁₆₁ et al. 1987). California scorpionfish migrate to deeper waters (120-360 ft) to spawn during
₁₆₂ May-August, with peak spawning occurring July. The species is oviparous, producing floating,
₁₆₃ gelatinous egg masses in which the eggs are embedded in a single layer (Orton 1955). and
₁₆₄ it is believed that spawning takes place just before, and perhaps after dawn, in the water
₁₆₅ column (Love et al. 1987). Tagging data suggest California scorpionfish return to the same
₁₆₆ spawning site, but information is not available on non-spawning season site fidelity.

₁₆₇ Little is known about California scorpionfish larvae. The CalCOFI survey observed 463
₁₆₈ California scorpionfish larvae from 1977-2000, with the majority at station close to Oxnard

¹⁶⁹ (east of the Channel Islands) (Moser et al. 2002). Higher densities of larvae have been
¹⁷⁰ observed in the CalCOFI stations throughout Baja, peaking south of Punta Eugenia from
¹⁷¹ July to September. The hatching length is reported as 1.9-2.0 mm (Washington et al. 1984)
¹⁷² and transformation length of greater than 1.3 cm (Washington et al. 1984) less than 2.1 cm
¹⁷³ (Moser 1996).

¹⁷⁴ 1.3 Map

map

¹⁷⁵ A map showing the scope of the assessment and depicting boundaries for fisheries or data
¹⁷⁶ collection strata is provided in Figure 1.

¹⁷⁷ 1.4 Ecosystem Considerations

ecosystem-considerations-1

¹⁷⁸ In this assessment, ecosystem considerations were not explicitly included in the analysis.
¹⁷⁹ This is primarily due to a lack of relevant data and results of analyses (conducted elsewhere)
¹⁸⁰ that could contribute ecosystem-related quantitative information for the assessment.

¹⁸¹ 1.5 Fishery Information

fishery-information

¹⁸² The hook-and-line fishery fishery off California developed in the late 19th century (Love et al.
¹⁸³ 2002).
¹⁸⁴ The rockfish trawl fishery was established in the early 1940s, when the United States became
¹⁸⁵ involved in World War II and wartime shortage of red meat created an increased demand for
¹⁸⁶ other sources of protein (Harry and Morgan 1961, Alverson et al. 1964).

¹⁸⁷ California scorpionfish comprise a minor part of the Californian sport and commercial fisheries
¹⁸⁸ (Love et al. 1987). Historically, California scorpionfish were taken commercially by hook and
¹⁸⁹ line and, occasionally, by round haul nets (Daugherty 1949). Scorpionfish were commonly
¹⁹⁰ caught around Santa Catalina Island during the late 19th Century with gillnets (Jordan
¹⁹¹ 1887). The 1937 Bureau of Commercial Fisheries report noted that California scorpionfish
¹⁹² had been a fairly important commercial species for a long time. The species was targeted by
¹⁹³ a few fishermen during the summer months, and was also taken as a bycatch in the rockfish
¹⁹⁴ fisheries. By 1949, Bureau of Marine Fisheries reported
¹⁹⁵ “[Scorpionfish] will even come to the surface to lights at night” and were also taken in round
¹⁹⁶ haul nets. At that time, scorpionfish were rarely targeted by fishermen except by a few
¹⁹⁷ specialists.

¹⁹⁸ More recently, commercial bottom longlines have been used to target spawning aggregations
¹⁹⁹ offshore of Long Beach (Love et al. 1987). Since the early 1990s, trawl catch has been

200 a substantial component of the commercial catch. Commercial landings have fluctuated
201 substantially over time, which could, in part, be due to changes in targeting and El Nio
202 events (Love et al. 1987). A high proportion of the catch landed in California during the
203 1960s and 1970s was taken from Mexican waters. In recent years, most of the catch has come
204 from around the Los Angeles region. In general, the majority of the commercial catch has
205 come from the Los Angeles region, except in the 1960s and 1970s when the majority of the
206 catch came from the San Diego region and Mexican waters.

207 They are most often taken by boat fishermen, but fairly large numbers are caught from
208 piers, jettys, and rocky shorelines. The CPFV effort has remained relatively constant over
209 a long period (1959-1998) (Dotson and Charter 2003). However, there appears to be a
210 shift in effort towards less utilized species, such as California scorpionfish, over the past
211 decade (Dotson and Charter 2003). Especially as catch limits for rockfish have become
212 more restricted commercial passenger fishing vessels (CPFV) operators target California
213 scorpionfish spawning aggregations during spring and summer (Love et al. 1987), and also
214 target California scorpionfish in the winter when other fisheries are closed.

215 California scorpionfish become a target species for day boats during the spawning months
216 when spawning aggregations can be located. There are a small number of boats that specialize
217 in targeting these aggregations. The spawning aggregations occur in deeper waters, often
218 times outside of the three nautical mile state jurisdiction. It is also unknown what fraction
219 of the population aggregates during the spawning season, e.g., all mature fish.

220 Aggregate mortality has been far below the Annual Catch Limits (ACL) established by the
221 2005 stock assessment. The ACL projections from the 2005 assessment assumed that the
222 entire ACL was being taken each year and as a result, the ACL for each subsequent year
223 declined despite under-attainment in reality.

224 In addition, in 2014, recreational catch was higher than expected. As a result, in 2014, the
225 combined recreational and commercial catch exceeded the OFL by 2mt (1%) resulting from
226 assumption that the ACL had been attained. Subsequently, action was taken to decrease the
227 recreational season by four months (September 1 - December 31). A catch only update of
228 the stock was undertaken in 2015 (Wallace and Budrick 2015) that imputed the actual catch
229 values since the last assessment, resulting in significant increase in the OFL and ACL.

230 Retrospectively, the catch in 2014 was well below the OFL as well as the ACL that would
231 have been in place had the ACL values from the actual attainment been in place in 2014.
232 Thus the stock has not been subject to overfishing since the original assessment or been in
233 an overfished condition historically and is considered healthy.

234 The season restriction in the recreational fishery remained in place as a precautionary measure
235 until the full assessment is completed to better inform the current status of the stock, catch
236 limits and regulations given the perspective provided.

237 1.6 Summary of Management History

summary-of-management-history

238 Prior to the adoption of the Pacific Coast Groundfish Fishery Management Plan (FMP) in
239 1982, California scorpionfish (*Scorpaena guttata*) was managed through a regulatory process
240 that included the California Department of Fish and Wildlife (CDFW) along with either
241 the California State Legislature or the Fish and Game Commission (FGC) depending on
242 the sector (recreation or commercial) and fishery. With implementation of the Pacific Coast
243 Groundfish FMP, California scorpionfish came under the management authority of the Pacific
244 Fishery Management Council (PFMC), being incorporated, along with all genera and species
245 of the family Scorpaenidae, into a federal rockfish classification and managed as part of
246 “Remaining Rockfish” under the larger heading of “Other Rockfish” (PFMC (2002, 2004),
247 Tables 31-39).

248 The ABCs provided by the PFMC’s Groundfish Management Team (GMT) in the 1980’s were
249 based on an analysis of commercial landings from the 1960’s and 1970’s. For this analysis,
250 most of the rockfishes were lumped into one large group. This analysis indicated that the
251 landings for rockfish in the Monterey-Conception area were at or near ABC levels (Pacific
252 Fishery Management Council 1993). To keep landings within these adopted harvest targets,
253 the Pacific Coast Groundfish FMP provided the Council with a variety of management tools
254 including area closures, season closures, gear restrictions, and, for the commercial sector,
255 cumulative limits (generally for two-month periods). With the implementation of a federal
256 groundfish restricted access program in 1994, allocations of total catch and cumulative limits
257 began to be specifically set for open access (including most of California’s commercial fisheries
258 that target California scorpionfish in Southern California) and limited entry fisheries (Pacific
259 Fishery Management Council 2002, 2004). As a result, in the later 1990’s as commercial
260 landings decreased and recreational harvest became a greater proportion of the available
261 harvest.

262 Beginning in 1997, California scorpionfish was managed as part of the *Sebastodes* complex-
263 south, Other Rockfish category. (*Sebastodes* complex-south included the Eureka, Monterey,
264 and Conception areas while *Sebastodes* complex-north included the Vancouver and Columbia
265 areas.) The PFMC’s rockfish management structure changed significantly in 2000 with the
266 replacement of the *Sebastodes* complex -north and -south areas with Minor Rockfish North
267 (now covering the Vancouver, Columbia, and Eureka areas) and Minor Rockfish South (now
268 Monterey and Conception areas only). The OY for these two groups (which continued to be
269 calculated as 0.50 of the ABC) was further divided (between north and south of 40°10' N.
270 latitude) into nearshore, shelf, and slope rockfish categories with allocations set for Limited
271 Entry and Open Access fisheries within each of these three categories (January 4, 2000, 65
272 FR 221; PFMC (2002), Tables 54-55). Because of its depth range and southern distribution,
273 California scorpionfish was included within the Minor Rockfish South, Other Rockfish ABC
274 and managed under the south of 40°10' N. latitude nearshore rockfish OY and trip limits
275 (PFMC (2002), Table 29).

276 Along with the above changes, in 2000 the southern area divided into two separate management
277 areas at Point Lopez, 36°00' N. latitude. This was followed in 2001 with the implementation

278 of the northern rockfish and lingcod management area between (40°10' N. latitude) and Point
279 Conception (34°27' N. latitude); and the southern rockfish and lingcod management area
280 between Point Conception and the U.S.- Mexico border. These were later revised starting
281 in 2004 with the northern rockfish and lingcod management area redefined as ocean waters
282 from the Oregon-California border (42°00' N. latitude) to 40°10' N. latitude, the central
283 rockfish and lingcod management area defined as ocean waters from 40°10' N. latitude to
284 Point Conception, and the southern rockfish and management area continuing to be defined
285 as ocean waters from Point Conception to the U.S.-Mexico border.

286 Cowcod Conservation Areas (CCAs) also were established in 2001 to reduce fishing effort for
287 cowcod rockfish (PFMC (2002), Table 29). These areas were closed to all recreational and
288 commercial fishing for groundfish except for minor nearshore rockfish1 (including California
289 scorpionfish) within waters less than 20 fathoms. In addition, Rockfish Conservation Areas
290 (RCAs) were established in 2003 to allow for the closure of specific area and depth ranges
291 along the West Coast for the purpose of reducing fishing effort for shelf and slope rockfish.
292 The California Rockfish Conservation Area (CRCA) was defined as those ocean waters south
293 40°10' N. latitude to the U.S.-Mexico border with different depth zones specified for the areas
294 north and south of Pt. Reyes (37°59.73' N. latitude).

295 During the late 1990's and early 2000's, major changes also occurred in the way that California
296 managed its nearshore fishery. The Marine Life Management Act (MLMA), which was passed
297 in 1998 by the California Legislature and enacted in 1999, required that the FGC adopt
298 an FMP for nearshore finfish. It also gave authority to the FGC to regulate commercial
299 and recreational nearshore fisheries through FMPs and provided broad authority to adopt
300 regulations for the nearshore fishery during the time prior to adoption of the nearshore finfish
301 FMP. Within this legislation, the Legislature also included commercial size limits for nine
302 nearshore species including California scorpionfish (10-inch minimum size) and a requirement
303 that commercial fishermen landing these nine nearshore species possess a nearshore permit.

304 Following adoption of the Nearshore FMP and accompanying regulations by the FGC in fall
305 of 2002, the FGC adopted regulations in November 2002 which established a set of marine
306 reserves around the Channel Islands in Southern California (which became effective April
307 2003) and adopted a nearshore restricted access program in December 2002 (which included
308 the establishment of a Deeper Nearshore Permit) to be effective starting in the 2003 fishing
309 year.

310 Although the Nearshore FMP provided for the management of the nearshore rockfish and
311 California scorpionfish, management authority for these species continued to reside with
312 the Council. Even so, for the 2003 and subsequent fishery seasons, the State provided
313 recommendations to the Council specific to the nearshore species that followed the directives
314 set out in the Nearshore FMP. These recommendations, which the Council incorporated into
315 the 2003 management specifications, included a recalculated OY for Minor Rockfish South
316 - Nearshore, division of the Minor Rockfish South - Nearshore into three groups (shallow
317 nearshore rockfish; deeper nearshore rockfish; and California scorpionfish), and specific harvest
318 targets and recreational and commercial allocations for each of these groups.

319 Also, since the enactment of the MLMA, the Council and State in a coordinated effort
320 developed and adopted various management specifications to keep harvest within the harvest
321 targets, including seasonal and area closures (e.g. the CCAs; a closure of Cordell Banks
322 to specific fishing), depth restrictions, minimum size limits, and bag limits to regulate the
323 recreational fishery and license and permit regulations, finfish trap permits, gear restrictions,
324 seasonal and area closures (e.g. the RCAs and CCAs; a closure of Cordell Banks to specific
325 fishing), depth restrictions, trip limits, and minimum size imits to regulate the commercial
326 fishery.

327 1.7 Management Performance

management-performance-1

328 Management performance table: (Table f)
329 A summary of these values as well as other base case summary results can be found in Table
330 i.

331 1.8 Fisheries off Mexico

fisheries-off-mexico

332 The California scorpionfish's range extends into to Abreojos, Baja California.
333 The species is also found in the northern Gulf of California and Guadalupe Island. No formal
334 stock assessments have been conducted for California scorpionfish in Mexican waters.

335 2 Assessment

assessment

336 2.1 Data

data

337 Data used in the California scorpionfish assessment are summarized in Figure 2.
338 A description of each data source is below.

339 2.1.1 Commercial Fishery Landings

commercial-fishery-landings

340 Commercial catches of California scorpionfish (often landed as "sculpin") are available back
341 to 1916. Landings from 1916 to 1935 are presented in CDFG Fish Bulletin No. 49 and
342 Bulletin No. 149 provides tabulated data from 1916 to 1968. Over 99% of the commercial
343 catches of California scorpionfish are from south of Pt. Conception.
344 Whenever possible, catches from north of Pt. Conception and also caught in Mexico but
345 landed in the U.S. were excluded from the commercial catch histories.

³⁴⁶ California Explores the Ocean(CEO) provides landings data taken from the CDFG Fish
³⁴⁷ Bulletins in electronic form, as well as electronic copies of all CDFG Fish Bulletins.

³⁴⁸ Statewide annual landings are available for California scorpionfish from 1916 to 1925, and
³⁴⁹ are assumed to be taken by hook-and-line. Data by area and month are given in a series of
³⁵⁰ bulletins, each bulletin usually providing information for a single year. Data by region and
³⁵¹ month is available for 1926 to 1986. The Santa Barbara region includes San Luis Obispo,
³⁵² Santa Barbara and Ventura counties. Catches from this region were included in the catch
³⁵³ history and comprised less than 10 mt for the period from 1926-1968 (the period when data
³⁵⁴ at the regional scale are available).

³⁵⁵ Catches from Mexico can be separated from the total catch starting in 1931, although the
³⁵⁶ CDFG Bulletins do not report catches originating from Mexican waters available for all years,
³⁵⁷ e.g., 1932-1934. It is assumed that before 1931 there was no catch taken from Mexican waters
³⁵⁸ landed in California.

³⁵⁹ The CALCOM database was queried (March 7, 2017) for commercial landing estimates of
³⁶⁰ California scorpionfish in California, 1969-2016. Landings were stratified by year, quarter,
³⁶¹ live/dead, market category, gear group, port complex, and source of species composition
³⁶² data (actual port samples, borrowed samples, or assumed nominal market category). All
³⁶³ CALCOM California scorpionfish landing data are either actual port samples or the nominal
³⁶⁴ California scorpionfish market category. However, catches in CALCOM do not separate out
³⁶⁵ catches originating from Mexican waters and landed at U.S. ports.

³⁶⁶ The Commercial Fisheries Information System (CFIS; maintained by CDFW) contains
³⁶⁷ California catch in pounds by gear and port for 1969 to 2016 (Figures). The CFIS data come
³⁶⁸ from landing receipts or “fish tickets” filled out by the markets or fish buyers as required by
³⁶⁹ the state for all commercial landings. The fish tickets include the CDFW block in which the
³⁷⁰ majority of the landings were caught.

³⁷¹ Landings with a block solely in Mexican waters (blocks >900) were removed from the catch
³⁷² history. Landings with reported blocks 877-882 with area in both U.S. and Mexican waters
³⁷³ were retained in the catch histories. The commercial catch is dominated by the hook-and-line
³⁷⁴ fishery (89% of total catches).

³⁷⁵ The catch by reported gear types: hook-and-line, fish pot, trawl, gill net, and other can be
³⁷⁶ found in Table 1. Catch taken by fish pot and other gears is added to the hook-and-line
³⁷⁷ catch in the stock assessment (30.6 mt from fish pot and 93.9 mt from other gears).

³⁷⁸ In the assessment, catch for 1916 to 1968 is taken from the CDFG Fish Bulletins. Catch by
³⁷⁹ gear for 1969 to 2004 is taken from CFIS.

³⁸⁰ **2.1.2 Commercial Discards**

commercial-discards

³⁸¹ Information on commercial discards from the West Coast Groundfish Observer Program
³⁸² (WCGOP) are available starting in 2004. The commercial fishery for California scorpionfish

³⁸³ has been minimal since the early 2003 (averaging 3.5 mt per year). The available length
³⁸⁴ composition data from the observed discards is minimal. . . .

³⁸⁵ 2.1.3 Sport Fishery Removals and Discards

sport-fishery-removals-and-discards

³⁸⁶ Data used in reconstructing the retained catch and discarded mortality for California scorpionfish in the California recreational fishery are from the Commercial Passenger Fishing
³⁸⁷ Vessel (CPFV) Logbooks (1932-2017), the Marine Recreational Fishery Statistical Survey
³⁸⁸ (MRFSS, 1980-2003) and the California Recreational Fishery Survey (CRFS, 2004-2017).

³⁸⁹ Total catch was accounted for including retained catch as well as the estimate of fish discarded dead assuming a 7% discard mortality rate approved for use in management in the
³⁹⁰ regulatory specifications for 2009-2010 (Pacific Fishery Management Council [2008](#)). The
³⁹¹ MRFSS and CRFS data provide estimates of mortality for four fishing “modes” including
³⁹² the Party/Charter Boat, Private/Rental Boat, Man Made (piers and jetties etc.) and Beach
³⁹³ and Bank modes.

³⁹⁴ While estimates of mortality from the Party/Charter (PC) boat mode is available from the
³⁹⁵ MRFSS and CRFS surveys for the Party/Charter Boat mode for 1980-2017, estimates from
³⁹⁶ the CRFS data from 2011-2017 and data from CPFV Logbook for 1932-2010 were used to
³⁹⁷ represent catch from this mode. The Party/Charter Phone Survey was used to estimate
³⁹⁸ effort used in producing effort estimates for CRFS between 2004 and 2010, which was subject
³⁹⁹ to negative bias due to the low of participation in the survey south of Point Conception.
⁴⁰⁰ The Coastal County Household Telephone Survey was used to estimate fishing effort for
⁴⁰¹ the MRFSS survey from 1980-2003 and were subject to potential positive avidity bias in
⁴⁰² participation by those contacted by the survey. As a result, the CPFV logbooks were used
⁴⁰³ to provide the reported number of retained and discarded California scorpionfish used to
⁴⁰⁴ estimate mortality from 1932-2010.

⁴⁰⁵ This is consistent with the catch based update conducted in 2015 as well as the original
⁴⁰⁶ assessment, both of which used estimates of catch from logbooks to represent catch in the
⁴⁰⁷ PC mode with the exception of the years after 2011 when effort estimates used in CRFS
⁴⁰⁸ estimates were derived from logbooks.

⁴⁰⁹ An underreporting adjustment reflecting an average 20% of logs not being submitted was
⁴¹⁰ applied to all estimates for the PC mode from 1932-2010. Annual average weights from this
⁴¹¹ mode for retained catch from the MRFSS or CRFS estimates for 1980-2010 and average
⁴¹² weight from 1980-1984 was applied to the preceding years. To estimate discard mortality
⁴¹³ for the PC mode, the annual average weight determined from lengths collected sampling
⁴¹⁴ onboard CPFVs by the CRFS survey for 2004-2010 were applied to the number of discards
⁴¹⁵ from the CPFV logbooks and the average weight over this entire period were applied to the
⁴¹⁶ preceding years for 1995-2003. For the period between 1980 and 1994, the MRFSS estimates
⁴¹⁷ for discards were used to reflect discarding due to the paucity of data on the number of
⁴¹⁸ discards from PC logbooks prior to 1995.

421 For all other modes, the MRFSS (1980-2003) and CRFS (2004-2017) based estimates of
422 retained catch and discard mortality were used. There was a lapse in MRFSS sampling
423 from 1990 through 1992, which for which retained catch and discard mortality was estimated
424 using the average of values three years before and three years after the lapse for all modes
425 other than the PC mode. For the PC mode, estimates of numbers of fish were available
426 from logbook data and average weight from the three years before and after this period were
427 applied to provide estimates for the PC mode.

428 Estimates of retained catch and discards were not available from the non-PC modes prior
429 to 1980, thus the ratio of catch in the PC mode to the other modes for 1980 through 1985
430 was used to provide an estimate of catch in the other modes in the years 1932-1979. In the
431 case of the PR mode, a linear ramp in the ratio adjustment between PC and PR modes was
432 applied between 1979 and 1966 from 0.55 in 1980 to 0.10 in 1965, reflecting the increase in
433 the relative proportion of catch contributed by the PR mode with time as more individuals
434 anglers purchased vessels, as recommended in the California Catch Reconstruction (Ralston
435 et al. 2010), and the ratio of 0.10 was assumed for all years prior. The ratio of PC estimates
436 to the MM and BB modes was assumed to constant and the average between 1980 and 1989
437 was applied from 1979 to 1932. Catch estimates from CPFV logbooks were not available
438 during the World War II era from 1941 until 1946 and catch was assumed to be zero for all
439 modes during this period. Estimates for retained catch and discarded mortality for 1935 to
440 1928 were estimated using a linear ramp from the value for 1936 to zero in 1928 for the PC
441 mode and ratios PC compared to other modes were used to proxy estimates for other modes
442 based on the resulting ramped values for the PC mode. The final time series of retained and
443 discarded landings is in Table 2.

444 2.1.4 Fishery-dependent Abundance Indices

fishery-dependent-abundance-indices

445 MRFSS Dockside Private Boat Index

446 The CDFW provided the CRFS private boat dockside sampling fisheries data from 2004
447 to 2016. The data went through several data quality checks to identify the best subset of
448 available data that are consistent over the time series and provide a representative relative
449 index of abundance once standardized. The dockside sampling of the private mode (PR mode
450 in RecFIN) consists of samples from a primary series of ports (PR1) where the majority
451 of fishing effort for this mode originates and a secondary series of ports with historically
452 low effort (PR2). Only PR1 samples were used for this index as the sampling forms for
453 the PR2 index have changed over time and the data could not reliably be collapsed to the
454 trip level. The dockside data consist of two types of data; Type 2 data contain records of
455 angler-reported catch, i.e., catch that was not observed by the sampler and Type 3 data
456 includes sampler-examined retained catch. Of the Type 2 reported catch for scorpionfish, less
457 than one percent were reported “thrown back dead” and five percent reported as retained
458 to eat. Given that the reported retained catch is a small fraction of the catch overall and
459 discard mortality of California scorpionfish is low, only the Type 3 examined catch are used
460 in the index.

461 The survey records the number of contributing anglers (number of anglers on the vessel for
462 the private mode), but does not contain data on hours fished. For this index, angler-day
463 was the assumed effort. The data were filtered to trips fishing with hook-and-line gear in
464 southern California. Trips with a primary fishing area of Mexico were also removed. The
465 CRFS dockside private boat records with these broad filters include 44,128 trips of which
466 3,802 caught California scorpionfish (8.6%).

467 The Stephens-MacCall approach was used to identify trips with a high probability of catching
468 California scorpionfish (Stephens and MacCall 2004). Prior to using the Stephens-MacCall
469 approach to select relevant trips a number of other filters were applied to the data to minimize
470 variability in CPUE estimates. Over the course of the time series only 45 trips from Santa
471 Barbara county encountered California scorpionfish, ranging from 0-10 trips a year. The
472 Stephens-MacCall approach was applied with and without trips from Santa Barbara and the
473 same species were identified as indicators and counter-indicators. For the final model prior to
474 Stephens-MacCall, trips from Santa Barbara were excluded, leaving 41,235 trips, and 3,747
475 of those caught California scorpionfish (Table 3).

476 Coefficients from the Stephens-MacCall analysis (a binomial GLM) are positive for species
477 which co-occur with California scorpionfish, and negative for species that are not caught with
478 California scorpionfish (Figure 4). Potentially informative species for the Stephens-MacCall
479 analysis were limited to species caught in at least one percent of all trips and caught in at
480 least five years. Some of these never occurred with California scorpionfish (strong ‘counter-
481 indicators’) and records with these species were removed from the data prior to estimation
482 of the index. Strong counter-indicators for the CRFS private boat index included yellowfin
483 tuna and dolphinfish.

484 A total of 6,673 trips were retained following the Stephens-MacCall filter, with all positive
485 California scorpionfish trips retained. The California scorpionfish recreational fishery in the
486 southern management area was closed for eight months in 2004 and nine months in 2005. The
487 majority of records from 2004 and 2005 are from the period when the fishery was closed and
488 were removed from the analysis (Figure 3). Records from months with the fishery was closed
489 from 2006-2016 were also excluded from the index since this index relies on sampler-examined
490 retained catch.

491 Catch per unite effort was modeled using a delta-GLM approach, where the catch occurrence
492 (binomial) component was modeled using a logit link function and the positive catch compo-
493 nent was modeled after log-transformation of the response variable, according to a normal
494 distribution with an identity link function. The units for CPUE are fish landed/anglers. A
495 gamma distribution for the positive catch component was also explored, but model selection
496 favored the lognormal model.

497 Model selection procedures selected the covariates *2-month wave* and *county* as important
498 for both the catch occurrence and positive catch component models for all data sets, along
499 with the categorical year factor used for the index of abundance (Table 4). The final index
500 indicates a decrease in relative abundance from 2006 to 2010, at which point the index is
501 relatively flat (Figure 5).

502 **CRFS Dockside Party/Charter Boat Index**

503 CPFV operators have been required to submit written catch logs with daily trips records of
504 catches to CDFW since 1935. The logbook data from 1936-1979 are available as monthly
505 summaries, which do not contain the level of detail needed for an index of abundance. CDFW
506 provided the CPFV logbook data from 1980-2016 (Charlene Calac, CDFW). Logbook data
507 from 1980-2016 contain records for each trip, including the fishing date, port of landing,
508 vessel name and number, CDFG block area fished (Figure 1), angler effort, number of fish
509 kept and discarded by species. As of 1994, operators were required to report the number
510 of fish discarded and lost to seals. Prior to 1994, it is assumed that all reported fish were
511 retained. Details and additional information on the historical logbook database can be found
512 in Hill and Schneider (1999).

513 The number of anglers on board the vessel and the hours fished are included in the database
514 for all years. Only retained fish are included in the index of abundance the the unit of effort
515 is angler hours. A number of data filters were applied to the data to account for possible
516 mis-reporting, e.g., trips reporting retained California scorpionfish in top 1% of the data
517 (>325 fish). Trips fishing outside of California scorpionfish habitat (reported as targeting
518 pelagic species) or trips reporting a block with a minimum depth deeper than 140 m were
519 also filtered out.

520 Because California scorpionfish is not a primary target species, boats with fewer than 10
521 trips retaining California scorpionfish were removed from the analysis. Data were also
522 filtered to only include catches reported from blocks South of Pt. Conception and north of
523 the U.S.-Mexico border (Figure 1, and blocks with at least 100 trips retaining California
524 scorpionfish and a total of 500 trips. A full description of the data filters is in Table 6. A
525 total of 432,868 trips were retained for the index of abundance, 202,937 of which caught
526 California scorpionfish.

527 Two different area factors were considered for the standardization, block and region.
528 The 60 retained blocks were split into nearshore regions north and south of San Pedro and
529 the northern and southern islands, for four regions. Both a delta model and a negative
530 binomial model were considered for index standardization. However, due to the large number
531 of records, the traditional jackknife routine to estimate uncertainty was not possible.

532 California scorpionfish were present in 47% of all trips, which warrants the use of a negative
533 binomial model. Factors considered were *year*, *month*, and *area* (either block or region). A
534 model with blocks and was selected over a model with region by 39,180 AIC. The final model
535 includes *year*, *month*, and *block* with a log link and effort as an offset (Table 7).

536 The standardized index shows a cyclic pattern, with period of higher CPUE (late 1980's to
537 early 1990's and late 1990s) and has shown a general downward trend since 2008 (Figure 9).
538 An interesting note is the similarity in standardized CPUE between the CPFV logbook index
539 and the CPFV dockside index (not used in the stock assessment model) from 1992-1997 (for
540 a Stephens-MacCall threshold of 0.1) (Figure 8).

541 **Party/Charter Boat Logbook Index**

542 **Onboard Observer Party/Charter Boat Index**

543 California implemented a statewide Onboard Observer Sampling Program in 1999, and began
544 measuring discarded fish in 2003 (Monk et al. 2014). The goal of the Onboard Observer
545 Sampling Program is to collect data including charter boat fishing locations, catch and
546 discard of observed fish by species, and lengths of discarded fish. The program samples the
547 commercial passenger fishing vessel (CPFV), i.e., charter boat or for-hire fleet and collects
548 drift-specific information at each fishing stop on an observed trip.

549 At each fishing stop recorded information includes start and end times, start and end location
550 (latitude/longitude), start and end depth, number of observed anglers (a subset of the total
551 anglers), and the catch (retained and discarded) by species of the observed anglers.

552 CDFW implemented a regulation of three hooks in 2000, which was reduced to (and remains
553 at) two hooks in 2001. CDFW also implemented a 10 inch size limit for California scorpionfish
554 in 2000. The length composition of retained in discarded California scorpionfish (both before
555 and after the minimum size restriction). Prior to 2001, there were no depth restrictions for
556 the southern California recreational fishery. Given these regulation changes, the data from
557 1999 and 2000 are excluded from the index.

558 From 2002 to 2005, the California scorpionfish fishery was closed from four to nine months of
559 the year. During these years, California scorpionfish were still encountered, but all discarded.
560 The onboard observer program provides the only available information on discards because
561 the sampler records both the retained and discarded catch at each fishing stop. The onboard
562 observer data are used to create two indices of abundance, one using only the discarded catch
563 and one using only the retained catch. The index of discarded catch is used as an index of
564 abundance for the recreational discard fleet, and the index derived from the retained catch is
565 treated a survey in the assessment model.

566 Prior to any analyses, drifts with erroneous or missing data were removed from the data
567 considered for the California scorpionfish index. Both of the indices derived from this dataset
568 were standardized using a delta-GLM modeling approach (Lo et al. 1992).

569 The locations of positive encounters were mapped, using the drift starting locations.
570 Regions of suitable habitat were defined by creating detailed hulls (similar to an alpha hull)
571 with a 0.01 decimal degree buffer around a location or cluster of locations.
572 Any portion of a region that intersected with land was removed. As an example of the buffers,
573 a region with only one positive encounter has an ellipsoid area of 3.22km². Each drift (both
574 positive and zero-catch) was assigned to the region with which it intersected. Drifts that
575 did not intersect with a region were considered structural zeroes, i.e., outside of the species
576 habitat, and not used in analyses.

577 **California CRFS Party/Charter Boat Index (Dockside)**

578 From 1980 to 2003 the MRFSS program sampled landings at dockside (called an “intercept”)
579 upon termination of recreational fishing trips. The program was temporarily suspended

580 from 1990-1992 due to lack of funding. For purposes of this assessment, the MRFSS time
581 series is truncated at 1998 due to overlap with an alternative index used to represent 1999
582 onward using onboard sampling data making analysis using the dockside data redundant
583 (see “Recreational Onboard Observer Surveys”). Only trips south of Point Conception were
584 included in the analysis as California scorpionfish are exceedingly uncommon in the catch to
585 the north. The California party and charter boat (a.k.a. “PC mode,” commercial passenger
586 fishing vessel, or CPFV) samples used in the present analysis provide catch and effort data
587 aggregated at the trip level. Each entry in the RecFIN Type 3 database corresponds to a
588 single fish examined by a sampler at a particular survey site. Since only a subset of the catch
589 may be sampled, each record also identifies the total number of that species possessed by
590 the group of anglers being interviewed. The number of anglers and the hours fished are also
591 recorded. Unfortunately the Type 3 data do not indicate which records belong to the same
592 boat trip. Because our aim is to obtain a measure of catch per unit effort (fish per angler
593 hour), it is necessary to separate the records into individual trips. For this reason trips must
594 be inferred from the RecFIN data. This is a lengthy process, and is outlined in Supplemental
595 Materials (“Identifying Trips in RecFIN”).

596 Since recreational fishing trips target a wide variety of species, standardization of the catch
597 rates requires selecting trips that are likely to have fished in habitats containing California
598 scorpionfish. The method of Stephens and MacCall (2004) was used to identify trips with a
599 high probability of catching California scorpionfish, based on the species composition of the
600 catch in a given trip. Prior to applying the Stephens-MacCall filter, we identified potentially
601 informative “predictor” species , i.e., those with sufficient sample sizes and temporal coverage
602 (at least 30 positive trips total, distributed across at least 10 years of the index) to inform
603 the binomial model. Coefficients from the Stephens-MacCall analysis (a binomial GLM) are
604 positive for species which co-occur with California scorpionfish, and negative for species that
605 are not caught with California scorpionfish.

606 Data for dockside sampling of 6295 commercial passenger fishing vessel (CPFV) trips south
607 of Point Conception by the Marine Recreational Fishery Statistical Survey (MRFSS) were
608 filtered using the Stephens-McCall method to identify trips with catch associated with
609 California scorpionfish and the resulting trips analyzed in a delta-GLM including year and
610 county to produce annual indices of abundance for the period 1980 through 1998 . To
611 eliminate trips targeting species caught near the surface for all or part of the trip where
612 California scorpionfish do not occur, prior applying the Stephens-MacCall filter, trips with
613 catch of bluefin tuna, yellowfin tuna, dorado, Pacific bonito, skipjack, albacore, chinook
614 salmon, coho salmon and bigeye tuna were removed. Trips with catch of yellowtail amberjack
615 were also removed since effort on such trips can often be focused in the surface and midwater
616 where California scorpionfish do not occur. In addition, trips with aggregate effort less below
617 and above 95% percentile (less than 2 and over 109.5 hours) were removed to exclude trips
618 for which either too little effort was exerted to be informative or longer trips that may make
619 an excessive contribution to the effort likely distributed over a number of targets only some
620 of which may co-occur with California scorpionfish biasing low the resulting CPUE. Lastly,
621 trips in Santa Barbara County were removed due the low number of positive samples for
622 California scorpionfish since it resides in the northern extent of their range and this is a

623 transition zone between biogeographic provinces in which the presence of more northerly
624 distributed species could adversely affect the ability of the Stephens-MacCall filtering method
625 to identify co-occurring species.

626 Removal of the aforementioned trips resulted in a total of 3968 trips to which the Stephens-
627 MacCall filtering method was applied. Species that composed less than 5% of the catch
628 were excluded from analysis to prevent these uncommon species from affecting correlations
629 identified using the algorithm. Chub mackerel, Pacific mackerel and barracuda were removed
630 as potential predictor species despite having weak positive correlations with California
631 scorpionfish since they are predominantly pelagic and their co-occurrence is not expected to
632 be predictive. As expected, positive indicators of California scorpionfish trips include several
633 species of nearshore rockfish, California sheephead, California halibut, Pacific sanddabs and
634 seabasses and counter-indicators include several species of deep-water rockfish (Figure 6).
635 While the filter is useful in identifying co-occurring or non-occurring species assuming all
636 effort was exerted in pursuit of a single target, the targeting of more than one target species
637 can result in co-occurrence of species in the catch that do not truly co-occur in terms of
638 habitat associations informative for an index of abundance, presenting a confounding influence
639 in selecting trips using the methods employed.

640 Two levels of filtering were applied using the Stephens- MacCall Filter. The Stephens-MacCall
641 filtering method identified the probability of occurrence (in this case 0.27) at which the rate
642 of false positives and false negatives for the presence of California scorpionfish were equal as
643 a heuristic for selecting a threshold for trips in appropriate habitat to be included in analysis.
644 The trips from this criteria for selection was compared to an alternative method including
645 the false positive trips as well as all positive trips for California scorpionfish supported by
646 the assumption that if California scorpionfish were caught in such trips, they must constitute
647 appropriate habitat justifying their inclusion. In addition, the false positives from a lower
648 probability of occurrence (0.10) that was considered to reflect a less stringent threshold
649 inclusive of more trips including a higher proportion of the false positive trips combined with
650 the positive trips from the entire data set was evaluated for comparison.

651 CPUE (number of fish per angler hour) was modelled using a “delta-GLM” model (Lo et
652 al. 1992, Stefnsson 1996). Model selection using Akaike Information Criterion (AIC) and
653 Bayesian Information Criteria (BIC) supported inclusion of year and region effects in both
654 the binomial and lognormal components of the index for both the model with false positives
655 from the 0.27 threshold and the 0.10 threshold. The addition of month effects (to allow for
656 seasonal changes in CPUE) did not improve model fit. The lognormal model was employed as
657 a result of the lower AIC values compared to the binomial model. The resulting index values
658 for 1989 were anomalously high compared to other years. In addition, the less stringent filter
659 of 0.10 resulted in a higher index value than 0.27, which was antithetical to the expectation
660 that including trips with fewer positive trips would decrease the CPUE. Further examination
661 of the number of California scorpionfish per trip by year showed a lower number of trips for
662 this year than others and a lower proportion of low catch trips explaining why exclusion of
663 low catch trips through application of the 0.27 index reduced the relative magnitude of the
664 1989 index value relative to other years. As a result of this anomalous result and the low

665 sample size, trips from 1989 were excluded from analysis.

666 The percentage of trips that caught California scorpionfish was 20.8% (828/3968) prior to
667 filtering with the Stephens-MacCall method, and 71.0% (828/1167) with the filter set to
668 0.27 and 26.7% (828/3099) with the filter set to 0.10, filtered data set. Residual-based
669 model diagnostics for the positive component of the index suggest the data generally met
670 the assumptions of the GLM (Figure 7). The resulting index is highly variable for both
671 thresholds, with consistent peaks in 1984 and 1998 (Figure 8).

672 The results of the models with each of the thresholds provided similar trends seen in Figure 4
673 along with the results from the CPFV logbook index. The trends differ from those resulting
674 from the CPFV logbook index early in the time series, but both show an increase in the
675 mid to late 1990s. The PC dockside index was excluded from further analysis in the model
676 given that the PC logbook index represents the same sector of the fishery and presumably
677 contains data from the some of the same trips, utilizes data for many thousands more trips,
678 and provides data from 1989 to 1992 omitted from the MRFSS data as a result of filtering
679 out 1989 and a lapse of sampling from 1990-1992.

680 2.1.5 Fishery-Independent Abundance Indices

`fishery-independent-abundance-indices`

681 Sanitation Districts Trawl Survey Index

682 Sanitation districts in southern California are required to conduct trawls as part of their
683 National Pollutant Discharge Elimination System (NPDES) permits. All sanitation districts
684 in southern California were contacted for data series. The two northernmost districts Goleta
685 and the City of Oxnard provided data, but no scorpionfish have been observed in either trawl
686 survey. The four other sanitation districts, Orange County, City of Los Angeles, Los Angeles
687 County, and the City of San Diego all encounter California scorpionfish.

688 Orange County Orange County Sanitation District provided trawl data from 1970-2015, and
689 the majority of sampling occurred in Quarter 1 and 3 (Jan-March and July-September). From
690 1970-1985 Quarter 2, sampling was based on a 10 minute tow time. As of 1985 Quarter 3
691 sampling was based upon a towed distance of 450m. Tow time was missing for approximately
692 half of the tows from 1985 Quarter 3 to present, and was imputed based on the mean tow
693 time of the sampling station. Two stations were removed that were frequently sampled, but
694 observed very few scorpionfish. Eleven stations (T0-T6,T10-T13) with long time series and
695 1,490 tows were retained for the analysis .

696 City of Los Angeles (Hyperion) The City of Los Angeles Sanitation District provided trawl
697 data from 1986-2016.

698 Years with fewer than ten samples were removed from the analysis (1986, 1987, and 1992).

699 Tow times were recorded starting in 1999, and assumed to be 10 minutes prior to 1999.

700 Stations sampled at least ten years were retained, which resulted in ten stations (A1, A3,

701 C1, C3, C6, C9A, D1T, Z2, Z3, Z4; 921 hauls) for the analysis. Haul depth was missing for
702 approximately half of the stations, and was imputed as the mean depth of other tows at
703 that station.

704 Los Angeles County (Palos Verdes) The Sanitation Districts of Los Angeles County provided
705 trawl data from 1972-2016 with quarterly sampling. Stations sampled in fewer than 10 years
706 or at 305m where California scorpionfish were never observed were removed from the analysis.
707 Non-standard and special study trawls were also removed, e.g., night trawl study in 1987.
708 Hauls were based on a 10 minute tow time. Twelve stations (stations at 23m, 61m, and 137m
709 for T0,T1,T4,T5) containing 1,848 tows were retained after initial filtering.

710 City of San Diego The City of San Diego Sanitation provided trawl data from 1985-2015.
711 Stations sampled in at least 15 years were retained for analysis, resulting in 14 stations
712 (SD1-SD14, SD17-21) and a total of 1,180 tows. A ten minute tow time is assumed for all
713 trawls.

714 NWFSC Trawl Survey Index

715 The Northwest Fishery Science Center has conducted combined shelf and slope trawl surveys
716 (hereafter referred as NWFSC trawl survey) since 2003, based on a random-grid design from
717 depths of 55 to 1280 meters. Additional details on this survey and design are available in the
718 abundance and distribution reports by Keller et al. (2008). Spatial locations of raw catch
719 rates (in log scale) are shown in Figure X1.

720 The proportions of positive catch haul and the raw catch rates of positive hauls by depth and
721 latitude are shown in Figure 14 and Figure 15, respectively. These figures show that more
722 scorpionfish were caught at shallow depth zones and in the southern latitude zones. Box
723 plots of length summary data by depth and sex (Figure 17) and by latitude and sex (Figure
724 17) show no evidences of different spatial distributions (by depth and latitude) by length or
725 by sex.

726 The numbers of total hauls and percentages of positive catch hauls by depth and latitude
727 zones are presented in Tables 17 and 18, respectively. Summaries of raw catch data by year
728 are listed in Table 19. Overall, catches of scorpionfish by the survey were very low with
729 less than 1mt fish caught during the entire 14 years of the survey. Bubble plots of length
730 frequency distribution by year and sex are presented in Figure 18.

731 Summaries of age data by year and sex are presented in Table 20. There were more males (n
732 = 529) being aged than females (n = 340), presumably indicating that there are more males
733 than females in the populations. The table also shows that mean ages and mean lengths
734 for both sexes decreased in recent years. Table 21 show five percentiles of fish aged by sex,
735 indicating more older males in the population. All aged data from the survey were used as
736 conditional age-at-length matrix in the assessment model.

737 Total biomass estimates from the survey were analyzed using the VAST program (Thorson
738 and Barnett 2017). The Q-Q goodness of fit plot and time series of total biomass estimates

739 are shown in Figures 19 and 20, respectively. The Q-Q plots shows generally good of fits
740 and the time series of biomass estimates indicates no significant trend with relatively large
741 uncertainties from the survey. The final survey index and log standard error used in the
742 assessment model are in Table 22.

743 **CSUN/VRG Gillnet Survey Index**

744 The CSUN/VRG gillnet survey was conducted from 1995-2008. Sites along the coast from
745 Santa Barbara to Newport were consistently sampled for the time series, as well as Catalina
746 Island. Gillnet sets from within Marina Del Rey and Catalina Harbor were removed from the
747 analysis.

748 Gillnets were All gillnets were the same length with six-25' panels (150' in length).
749 The majority of samples were collected using a net with 1", 1.5", 2" square mesh, each mesh
750 was on 2 panels.

751 Perp/para was whether or not the net was set perpendicular or parallel to shore.

752 **Southern California Bight 2013 Regional Monitoring Project Trawl Survey Index**

753 **2.1.6 Other data sources considered**

other-data-sources-considered

754 *Northwest Fisheries Science Center (NWFSC) shelf-slope survey*

755 This survey is referred to as the “combo,” conducted annually since 2003.

756 The survey consistently covered depths between 30 and 700 fm.

757 *Alaska Fisheries Science Center (AFSC) shelf survey*

758 The survey, often referred to as the “triennial” survey was conducted every third year between
759 1977 and (and conducted in 2004 by the NWFSC using the same protocols). The triennial
760 survey trawls in depths of 30 to 275 fm.

761 *California Cooperative Oceanic Fisheries Investigations (CalCOFI) Survey* Only 16 positive
762 tows in the core area (lines 77-93) of California scorpionfish.

763 The majority of the 335 positive tows occurred in Mexico, south of Punta Eugenia Baja
764 California and are likely a combination of California scorpionfish and other *Scorpaena* species.
765 Prior to 1965, *Scorpaena* samples were not speciated.

766 *Generating Station Impingement Surveys*

767 Data from the southern California generating station surveys were provided by Eric Miller
768 (xxx). There are five generating stations that conduct normal operation and heat treatment
769 surveys: Scattergood Generating Station (SGS), El Segundo Generation Station (ESGS),
770 Redondo Beach Generating Station (RBGS), Huntington Beach Generatig Station (HBSGS),
771 and San Onofre Generatin Station (SONGS).

772 The generating stations all draw in seawater through an intake system for once-through
773 cooling water. Each generating station draws in water from different depths and distances
774 from shore: SGS draws from 500 m offshore at 6 m depth, ESBS draws from 700 m offshore
775 at 9.8 m depth, RBGS draws from 289 m offshore at 13.7 m depth, HBGS draws from 500 m
776 offshore at 5 m depth, and SONGS has two intake systems 960 m and 900 m offshore and at
777 9 m and 8m depth, respectively (Miller et al. 2009).

778 The two surveys conducted are normal operations surveys and heat treatment surveys. For
779 normal operations surveys, the intake screens are rotated and cleaned to start the survey. All
780 of the impinged fish are washed off the screen at this time and discarded. when the intake
781 screens stop running, the survey begins. The generating station then operates as normal for
782 24 hours, which includes operating and washing the screens as usual (typically every eight
783 hours). The screens are then operated and washed again after a second 24 hours has elapsed.
784 Any specimens washed off the screens during the 48 hour study period are retained. The
785 total sample is processed to identify, count, weigh, measure the fish and macroinvertebrates.
786 There is no information on the water flow collected during the 48 hour period of the normal
787 operations survey. Most fish enter the the generating station and swim in the forebay until
788 either getting exhausted or impinged. Does that sound about right?

789 During a heat treatment,

790 data, it's my understanding that the screens are rotated and washed off per normal operating
791 procedures right up until the heat treatment takes place. Therefore, only the fish remaining
792 in the forebay and those impinged since the last screen rotation are counted in the heat
793 treatment. The flow between heat treatments has previously been used to standardize the
794 catch. However, I don't see that as very useful since the fish killed in the heat treatment are
795 not the total representative sample since the last heat treatment.

796 2.1.7 Biological Parameters and Data

biological-parameters-and-data

797 Conversion factors California scorpionfish do not have a forked tail, therefore total length
798 and fork length are equal. Love et al. (1987) provide conversion factors between standard
799 length (SL) and total length (TL). $TL = 1.21SL + 1.02$ and $SL = 0.82TL - 0.69$.

800 Standard and total lengths of 163 California scorpionfish were available from a halibut trawl
801 survey in southern California (Steve Wertz, CDFW). The conversion from SL to TL from
802 these data was estimated at $TL = 1.2225SL + 0.7773$.

803 The conversion originating from the halibut trawl data was used in this assessment due to
804 the fact that the original data from Love et al. (1987) are not available.

805 The majority of available length composition data were measured to total length, except
806 for three of the sanitation district trawl surveys, the Southern California Bight Regional
807 Monitoring Program trawl survey, and the CSUN/VRG gillnet survey (gillnet survey).

808 Maunder et al. (2005) converted all data to standard length due to clumping of data when
809 length data are only available to the nearest centimeter. However, the same is true for the
810 conversion from TL to SL when data are available to the nearest centimeter. All length data
811 for this assessment are in TL. The Sanitation District of Orange county and the VRG gillnet
812 study measured SL to the nearest mm.

813 To avoid missing length bins (specifically 18, 23, 29cm) in the conversion from SL to TL,
814 0.5 was first subtracted from each SL and a random uniform number ($U[0,1]$) was added to
815 the SL measurement. All TL measurements were rounded to the nearest length centimeter
816 length bin. A comparison of the length distributions

817 Length And Age Compositions

818 Include: Sample size information for length and age composition data by area, year, gear,
819 market category, etc., including both the number of trips and fish sampled.

820 Length compositions were provided from the following sources, with brief descriptions below:

- 821 • CDFW market category study (*commercial dead fish, 1996-2003*)
- 822 • CALCOM (*commercial dead fish, 2013-2016*)
- 823 • CDFW onboard observer (*recreational charter discards, 2003-2016*)
- 824 • Ally onboard observer study (*recreational charter discards, 1984-1989*)

837 *Recreational: California MRFSS And CRFS Length Composition Data* Individual fish lengths
838 recorded by MRFSS (1980-2003) and CRFS (2004-2011) samplers were downloaded from the
839 RecFIN website (www.recfin.org). CRFS data from 2012-2014 were obtained directly from
840 CDFW.

841 *Commercial: PacFIN*

842 *Research: NWFSC shelf-slope survey*

843 *Research: NWFSC slope survey*

844 **Age Structures** Age data were provided from the NWFSC trawl survey from 2005-2016.

845 Length-at-age was initially estimated external to the population dynamics models using the
846 von Bertalanffy growth curve (Bertalanffy 1938), $L_i = L_\infty e^{(-k[t-t_0])}$, where L_i is the length
847 (cm) at age i , t is age in years, k is rate of increase in growth, t_0 is the intercept, and L_∞ is
848 the asymptotic length.

849 **Aging Precision And Bias**

850 **Weight-Length**

851 The weight-length relationship is based on the standard power function: $W = \alpha(L^\beta)$ where
852 W is individual weight (kg), L is length (cm), and α and β are coefficients used as constants.

853 **Maturity And Fecundity**

854 **Natural Mortality** Hamel (2015) developed a method for combining meta-analytic ap-
855 proaches to relating the natural mortality rate M to other life-history parameters such as
856 longevity, size, growth rate and reproductive effort, to provide a prior on M . In that same
857 issue of ICESJMS, Then et al. (2015), provided an updated data set of estimates of M and
858 related life history parameters across a large number of fish species, from which to develop
859 an M estimator for fish species in general. They concluded by recommending M estimates
860 be based on maximum age alone, based on an updated Hoenig non-linear least squares
861 (nls) estimator $M = 4.899 * A_{max}^{-0.916}$. The approach of basing M priors on maximum age
862 alone was one that was already being used for west coast rockfish assessments. However,
863 in fitting the alternative model forms relating $-0.916M$ to A_{max} , Then et al. (2015) did
864 not consistently apply their transformation. In particular, in real space, one would expect
865 substantial heteroscedasticity in both the observation and process error associated with the
866 observed relationship of M to A_{max} . Therefore, it would be reasonable to fit all models under
867 a log transformation. This was not done. Reevaluating the data used in Then et al. (2015) by
868 fitting the one-parameter A_{max} model under a log-log transformation (such that the slope is
869 forced to be -1 in the transformed space (as in Hamel (2015)), the point estimate for M is:

$$M = \frac{5.4}{A_{max}} \quad (1)$$

870 The above is also the median of the prior. The prior is defined as a lognormal with mean
871 $\ln \frac{5.4}{A_{max}}$ and SE = 0.4384343. Using a maximum age of 21 the point estimate and median of
872 the prior is 0.2545, which is used as a prior for females in the assessment model.

873 **Sex ratios**

874 **2.1.8 Environmental Or Ecosystem Data Included In The Assessment**
environmental-or-ecosystem-data-included-in-the-assessment

875 **2.2 History Of Modeling Approaches Used For This Stock**
history-of-modeling-approaches-used-for-this-stock

876 **2.2.1 Previous Assessments**
previous-assessments

877 **2.2.2 2005 Assessment Recommendations**
assessment-recommendations

878 Include: Response to STAR panel recommendations from the most recent previous assessment.

879 **Recommendation 1:** The sanitation surveys conducted to track the impact
880 of sewage outfall provided a fishery independent index of abundance for
881 scorpionfish. This data source should be more fully explored for other
882 near-shore species of recreational or commercial interest. Methods should
883 be developed to produce a more statistically rigorous index from the
884 separate surveys.

885

886 STAT response: Data from all sanitation districts in southern California were obtained
887 for this assessment. All of the data were pooled across surveys to develop one index of
888 abundance using the delta-GLM method

889 **Recommendation 2:** An age, growth and maturity study for scorpionfish is
890 needed. Although there has been previous research on scorpionfish age and
891 growth, the available information is not appropriate for stock assessment
892 modeling.

893

894 STAT response: Age data are available from the NWFSC trawl survey from 2005-2016.
895 THere have been no additional studies on growth or maturity for California scorpionfish
896 since the 2005 assessment.

897 **Recommendation 3:** Location information for the historic groundfish data of all
898 species is currently available, in hard copy form only, from the California
899 Department of Fish and Game. Putting this information into electronic
900 format would greatly improve the ability to assign catches of all species to
901 specific stocks on a trip-by-trip basis.

902

903 STAT response: The location-sepcific catches referred to above have been key-punched
904 and are available in electornic form from the SWFSC, Santa Cruz.

905 **Recommendation 4:** The SS2 model should be modified to allow for projections
906 of user-specified recruitment at user defined values. It would be most

907 **helpful if the default harvest policies were then recalculated automatically**
908 **for these user-specified recruitments.**

910 STAT response: The status of this within Stock Synthesis is unknown.

911 **2.3 Model Description**

model-description

912 **2.3.1 Transition To The Current Stock Assessment**

transition-to-the-current-stock-assessment

913 Include: Complete description of any new modeling approaches

914 Below, we describe the most important changes made since the last full assessment and
915 explain rationale for each change.:

916 1. Change No. 1. *Rationale*: blah blah blah.

917 2. Change No. 2. *Rationale*: blah blah blah.

918 3. Change No. 3. *Rationale*: Continue list as needed.

919 **2.3.2 Definition of Fleets and Areas**

definition-of-fleets-and-areas

920 We generated data sources for each of the models. Fleets by model include:

921 **Model Region 1 or remove this line if only one model**

922 *Commercial*: The commercial fleets include...

923 *Recreational*: The recreational fleets include...

924 *Research*: Research derived-data include...

925 **2.3.3 Summary of Data for Fleets and Areas**

summary-of-data-for-fleets-and-areas

926 **2.3.4 Modeling Software**

modeling-software

927 The STAT team used Stock Synthesis 3 version 3.30.0.4 by Dr. Richard Methot at the NWFSC.
928 This most recent version was used, since it included improvements and corrections to older
929 versions. The r4SS package (GitHub release number v1.27.0) was used to post-processing
930 output data from Stock Synthesis.

931 **2.3.5 Data Weighting**

data-weighting

932 Citation for Francis method (Francis 2011)

933 Citation for Ianelli-McAllister harmonic mean method (McAllister and Ianelli 1997)

934 **2.3.6 Priors**

priors

935 Citation for Hamel prior on natural mortality (Hamel 2015)

936 **2.3.7 General Model Specifications**

general-model-specifications

937 Model data, control, starter, and forecast files can be found in Appendices A-D.

938 **2.3.8 Estimated And Fixed Parameters**

estimated-and-fixed-parameters

939 A full list of all estimated and fixed parameters is provided in Tables.... Estimated and fixed
940 parameters tables currently read in from .csv file, EXAMPLE: Table ??

941 **2.4 Model Selection and Evaluation**

model-selection-and-evaluation

942 **2.4.1 Key Assumptions and Structural Choices**

key-assumptions-and-structural-choices

943 Include: Evidence of search for balance between model realism and parsimony.

944 Comparison of key model assumptions, include comparisons based on nested models (e.g.,
945 asymptotic vs. domed selectivities, constant vs. time-varying selectivities).

946 **2.4.2 Alternate Models Considered**

alternate-models-considered

947 Include: Summary of alternate model configurations that were tried but rejected.

948 **2.4.3 Convergence**

convergence

949 Include: Randomization run results or other evidence of search for global best estimates.

950 Convergence testing through use of dispersed starting values often requires extreme values to
951 actually explore new areas of the multivariate likelihood surface. Jitter is a SS option that
952 generates random starting values from a normal distribution logically transformed into
953 each parameter's range (Methot 2015). Table 31 shows the results of running 100 jitters for
954 each pre-STAR base model....

955 **2.5 Response To The Current STAR Panel Requests**

response-to-the-current-star-panel-requests

956 **Request No. 1: Add after STAR panel.**

957

958 **Rationale:** Add after STAR panel.

959 **STAT Response:** Add after STAR panel.

960 **Request No. 2: Add after STAR panel.**

961

962 **Rationale:** Add after STAR panel.

963 **STAT Response:** Add after STAR panel.

964 **Request No. 3: Add after STAR panel.**

965

966 **Rationale:** Add after STAR panel.

967 **STAT Response:** Add after STAR panel.

968 **Request No. 4: Example of a request that may have a list:**

969

- 970 • **Item No. 1**
971 • **Item No. 2**
972 • **Item No. 3, etc.**

973 **Rationale:** Add after STAR panel.

974 **STAT Response:** Continue requests as needed.

975 **2.6 Model 1**

model-1

976 **2.6.1 Model 1 Base Case Results**

model-1-base-case-results

977 Table ??

model-1-retrospective-analysis

981 **2.6.4 Model 1 Likelihood Profiles**

model-1-likelihood-profiles

982 **2.6.5 Model 1 Harvest Control Rules (CPS only)**

model-1-harvest-control-rules-cps-only

983 **2.6.6 Model 1 Reference Points (groundfish only)**

model-1-reference-points-groundfish-only

984 Intro sentence or two....(Table 33).

985 Equilibrium yield at the proxy F_{MSY} harvest rate corresponding to $SPR_{50\%}$ is 205.4 mt.
986 Table e shows the full suite of estimated reference points for the northern area model and
987 Figure j shows the equilibrium yield curve.

988 **3 Harvest Projections and Decision Tables**

harvest-projections-and-decision-tables

989 Table f

990 **Model 1 Projections and Decision Table (groundfish only) (Table 34**

991 Table h

992 **Model 2 Projections and Decision Table (groundfish only)**

993 **Model 3 Projections and Decision Table (groundfish only)**

4 Regional Management Considerations

`regional-management-considerations`

- 995 1. For stocks where current practice is to allocate harvests by management area, a
996 recommended method of allocating harvests based on the distribution of biomass should
997 be provided. The MT advisor should be consulted on the appropriate management
998 areas for each stock.
- 999 2. Discuss whether a regional management approach makes sense for the species from a
1000 biological perspective.
- 1001 3. If there are insufficient data to analyze a regional management approach, what are the
1002 research and data needs to answer this question?

5 Research Needs

`research-needs`

- 1004 1. Research need No. 1
- 1005 2. Research need No. 2
- 1006 3. Research need No. 3
- 1007 4. etc.

6 Acknowledgments

`acknowledgments`

1008 1009 Include: STAR panel members and affiliations as well as names and affiliations of persons
1010 who contributed data, advice or information but were not part of the assessment team. Not
1011 required in draft assessment undergoing review. We thank Kevin Lee for the use of the cover
1012 photo for this document.

1013 **7 Tables**

Table 3: Recreational private mode dockside data sample sizes at each data filtering step. The bold value indicates the final sample size used for delta-GLM analysis.

Filter	Criteria	Sample size (no. positive trips)	Sample size (no. of trips)	tab:Fleet4_RecPR_dockside_filter
Entire dataset				108,171
General data filters	CRFS-PR1 survey only, Southern California only (sub_reg = 1), Hook and line gear only (geara = 'H'), Ocean only (Area_X = 1 or 2)	3,802	43,956	
Region	Remove trips from Santa Barbara	3,757	42,956	
Year	Remove 2004-2005; fishery closed majority of year	3,094	33,770	
Closed fishery	Remove remaining trips when fishery closed	3,056	32,236	
Rare and co-occurring species	Remove trips with yellowfin tuna and dolphinfish and species present in $\geq 1\%$ of all trips and in at least 5 years of data	3,056	30,033	
Stephens-MacCall	Retain all positive trips, plus "False Positives" (trips predicted to be in California scorpionfish habitat, but with no California scorpionfish retained)	3,056	4,873	

Table 4: AIC values for each model in the recreational private mode dockside sample index.

Model	Binomial	Lognormal
Year	6182.366	8103.204
Year + County	5862.9	8003.9
Year + Wave	6091	8092.2
Year + County + Wave	5792.29	8000.45

Table 6: Recreational CPFV logbook sample sizes at each data filtering step. The bold value indicates the final sample size used for delta-GLM analysis.

Filter	Criteria	tab:Fleet5_RecPC_CPFVlogbook_filter
		Sample size (no. of trips)
All CA data	No filter	1,164,662
Gear	Remove trips reported as diving, mooching or trolling	959,740
Effort or missing data	Remove trips with missing effort or species information	930,233
Year	Remove 2017, remaining years 1980-2016	929,781
Region	Remove trips north of Pt. Conception and in Mexico	568,222
Fish encountered	Remove trips reporting number of retained fish greater than in the 99% quantile (>325 fish)	564,433
Target species	Remove trips targeting sharks, striped bass, sturgeon, tun, misc. bay, and potluck	558,872
Single-species trips	Filter trips reporting catches of only species and that one species in <100 trips	558,833
Offshore trips	Remove trips catching yellowtail, tunas, and dolphinfish that were not designated as offshore trips	475,492
Vessel	Remove trips by vessels that had fewer than 10 trips catching scorpionfish	466,023
Anglers	Remove trips with number of anglers < the 1% and > the 99% quantile (retain 5-75 anglers)	452,938
Depth	Remove trips in blocks with a minimum depth of >140m	443,929
Scorpionfish targets	Blocks with at least 100 scorpionfish trips	433,248
Sample size	Blocks with at least 500 trips	432,868

Table 9: Recreational onboard observer data sample sizes at each data filtering step. The bold value indicates the final sample size used for delta-GLM analysis. The same sample data were used for the discard-only index and the retained-only catch indices

Filter	Criteria	Sample size (no. positive trips)	Sample size (no. of trips)
Initial SQL filtering		6,475	59,192
Habitat filter	Remove drifts >1000 m of alpha hull buffer, remove "reefs" with <0 drifts or 5% positives, or in CCA	6,365	30,987
Exclude 1999 and 2000	Management changes (depth and gear restrictions)	5,986	29,577
Depth	Remove upper and lower 1% of data (retain 26-330ft)	5,921	29,002
Minutes Fished	Remove upper and lower 1% of data (retain 4 - 155 minutes)	5,780	28,460
Observed Anglers	Remove upper and lower 1% of data (retain 4 - 15 anglers)	5,679	27,946
Boats	Include boats encountering scorpionfish in at least 3 years; at least 30 drifts and 10 with scorpionfish	5,509	26,805
Second depth filter	Remove anything >100 m after looking at 20 m depth bins	5,507	26,733

Table 18: Summaries of catch statistics of California scorpionfish by latitude zones from NWFSC trawl survey between 2003 and 2016.

Latitude zone	Total catch (kg)	Raw CPUE (kg/ha)	tab:Fleet8_NWFSCtrawl_catchlat
32.50	156.30	1.59	
33.00	274.90	2.60	
33.50	257.70	0.93	
34.00	270.10	0.73	
34.50	0.10	0.00	

Table 19: Summaries of haul statistics of California scorpionfish from NWFSC trawl survey between 2003 and 2016.

Year	No. hauls	No. positive hauls	Percent positive hauls	Total catch (kg)	Raw CPUE (kg/ha)
2003	33	9	27.30	28.20	0.51
2004	37	12	32.40	73.20	1.02
2005	37	8	21.60	58.50	0.90
2006	42	11	26.20	15.10	0.23
2007	50	12	24.00	81.30	1.03
2008	51	12	23.50	16.20	0.22
2009	58	10	17.20	217.50	2.60
2010	53	10	18.90	20.00	0.23
2011	51	16	31.40	64.00	0.93
2012	61	9	14.80	102.40	1.07
2013	25	8	32.00	182.70	4.85
2014	49	6	12.20	23.00	0.32
2015	50	14	28.00	52.50	0.59
2016	58	12	20.70	24.70	0.28

Table 20: Summary statistics of age data by year and sex from NWFSC trawl survey between 2005 and 2016. The last raw shows total numbers of fish aged by sex.

Year	No. aged	Mean age (year)	Mean length (cm)	No. aged	Mean age (year)	Mean length (cm)
2005	38	7.70	28.30	37	9.20	26.00
2006	12	5.50	25.60	33	8.60	24.40
2007	19	6.60	26.50	49	7.10	24.60
2008	19	5.70	25.80	30	8.00	24.50
2009	33	4.30	24.10	97	7.10	23.20
2010	20	8.50	27.60	22	8.90	24.80
2011	42	4.80	24.40	74	7.60	23.60
2012	30	9.60	28.60	36	9.30	25.00
2013	28	6.30	27.00	39	3.70	22.40
2014	32	5.70	24.40	41	6.00	22.20
2015	20	3.20	20.40	34	5.20	21.30
2016	47	2.70	21.10	37	4.90	20.60
Sum	340			529		

Table 21: Ages at five percentiles by sex from NWFSC trawl survey between 2005 and 2016, indicating more older males in the population.

Percentile	Female age at percentile	Male age at percentile
50.00	4.00	6.00
90.00	12.00	14.20
95.00	15.10	16.60
97.50	19.00	19.00
99.00	20.20	21.70

Table 22: The NWFSC trawl survey index.

Year	Index	Log-scale SE
2003	615.6453	0.5708
2004	1000.1240	0.4503
2005	936.2185	0.5943
