90 Data and Assessment

data-and-assessment

91 California scorpionfish was assessed in 2005 (Maunder et al. 2005) using Stock Synthesis
 92 II version 1.18. This assessment uses the newest version of Stock Synthesis (3.30.0.4). The
 93 model begins in 1916, and assumes the stock was at an unfished equilibrium that year.

94 Map of assessment region: (Figure e).

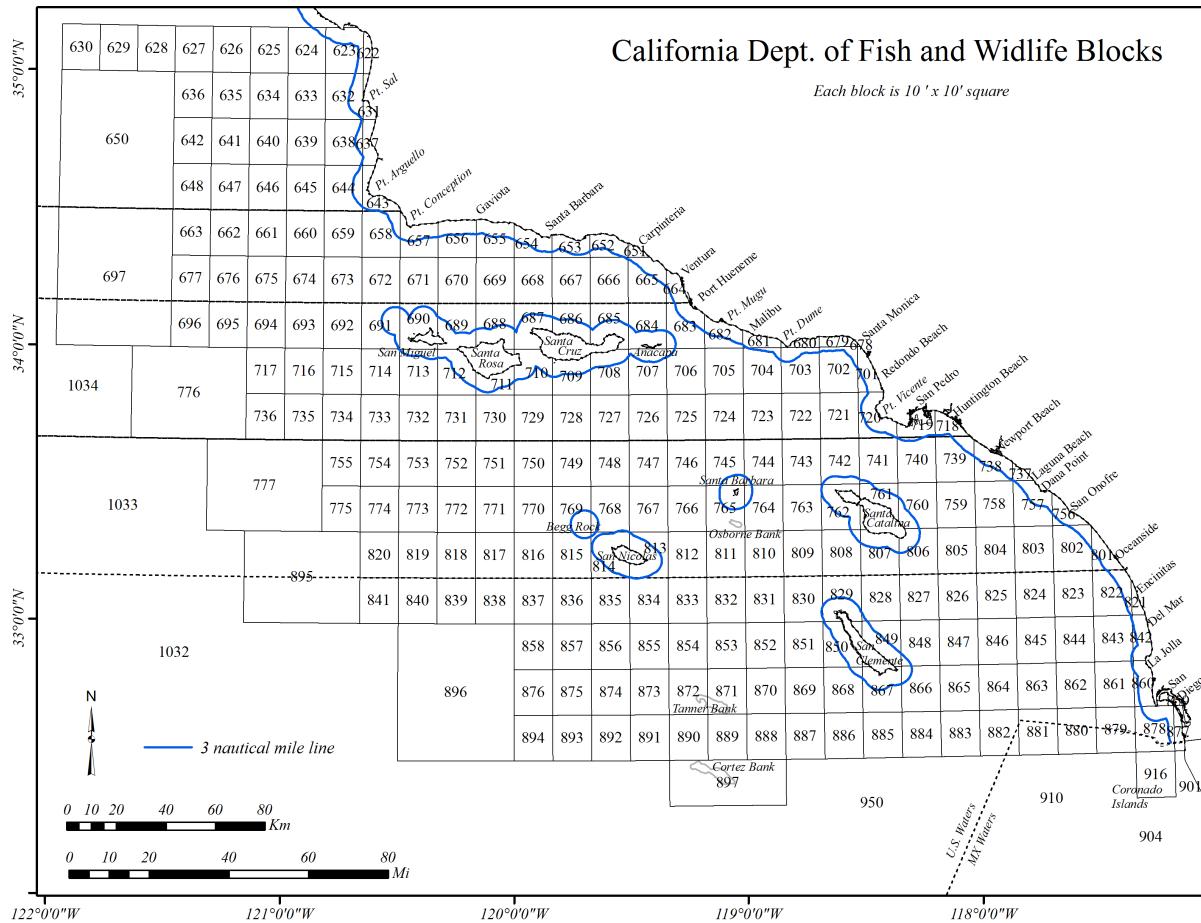

Figure e: Map depicting the boundaries for the base-case model. [fig:assess_region_map](#)

95 **Stock Biomass**

stock-biomass

- 96 Spawning output Figure: Figure [f](#)
 97 Spawning output Table(s): Table [b](#)
 98 Relative depletion Figure: Figure [g](#)

99 The estimated relative depletion level (spawning output relative to unfished spawning output)
 100 of the the base-case model in 2016 is 55.6% (~95% asymptotic interval: ± 40.5%-70.7%)
 101 (Figure [g](#)).

Table b: Recent trend in beginning of the year spawning output and depletion for the base model for California scorpionfish.

Year	Spawning Output (mt)	~ 95% confidence interval	Estimated depletion	~ 95% confidence interval
2008	649.288	(339.09-959.49)	0.731	(0.554-0.908)
2009	632.086	(332.7-931.47)	0.712	(0.542-0.881)
2010	599.904	(317.76-882.05)	0.676	(0.518-0.833)
2011	570.013	(305.72-834.31)	0.642	(0.498-0.786)
2012	546.582	(296.38-796.78)	0.616	(0.484-0.747)
2013	511.635	(276.25-747.02)	0.576	(0.454-0.698)

¹⁰⁵ **Exploitation status**

exploitation-status

¹⁰⁶ Exploitation Tables: Table d Exploitation Figure: Figure i).

¹⁰⁷ A summary of California scorpionfish exploitation histories for base model is provided as
¹⁰⁸ Figure .

Table d: Recent trend in spawning potential ratio and exploitation for California scorpionfish in the base model. Fishing intensity is (1-SPR) divided by 50% (the SPR target) and exploitation is F divided by F_{SPR}.

Year	Fishing intensity	~ 95% confidence interval	Exploitation rate	~ 95% confidence interval
2007	0.53	(0.29-0.78)	0.08	(0.04-0.11)
2008	0.46	(0.23-0.69)	0.06	(0.03-0.09)
2009	0.50	(0.26-0.75)	0.07	(0.04-0.1)
2010	0.49	(0.26-0.73)	0.07	(0.04-0.1)
2011	0.51	(0.27-0.75)	0.07	(0.04-0.1)
2012	0.57	(0.32-0.83)	0.08	(0.05-0.12)
2013	0.58	(0.32-0.84)	0.09	(0.05-0.13)
2014	0.64	(0.37-0.91)	0.10	(0.05-0.14)
2015	0.53	(0.28-0.78)	0.07	(0.03-0.1)
2016	0.50	(0.26-0.74)	0.05	(0.02-0.08)

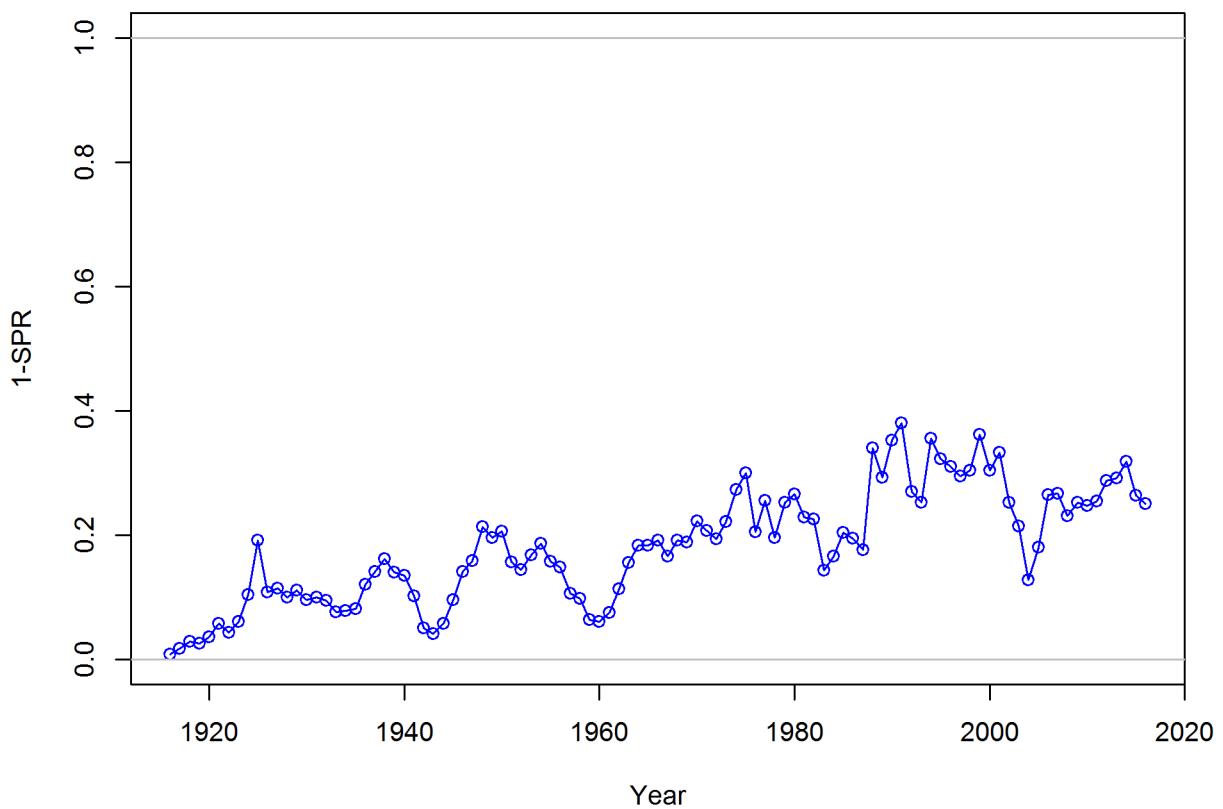

Figure i: Estimated spawning potential ratio (SPR) for the base-case model. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis. The management target is plotted as a red horizontal line and values above this reflect harvests in excess of the overfishing proxy based on the $\text{SPR}_{50\%}$ harvest rate. The last year in the time series is 2016. | [fig:SPR_all](#)

109 **Ecosystem Considerations**

ecosystem-considerations

110 In this assessment, ecosystem considerations were. . . .

111 **Reference Points**

reference-points

112 This stock assessment estimates that California scorpionfish in the base model are above the
113 biomass target, but above the minimum stock size threshold. Add sentence about spawning
114 output trend. The estimated relative depletion level for Model 1 in 2016 is 55.6% (~95%
115 asymptotic interval: ± 40.5%-70.7%, corresponding to an unfished spawning output of 493.509
116 mt (~95% asymptotic interval: 242.88-744.14 mt) of spawning output in the base model
117 (Table e). Unfished age 1+ biomass was estimated to be 2218.6 mt in the base case model.
118 The target spawning output based on the biomass target ($SB_{40\%}$) is 355.2 mt, which gives
119 a catch of 218.4 mt. Equilibrium yield at the proxy F_{MSY} harvest rate corresponding to
120 $SPR_{50\%}$ is 205.4 mt.

Table e: Summary of reference points and management quantities for the base case base model.

Quantity	Estimate	95% Confidence Interval
Unfished spawning output (mt)	888	(617.9-1158.1)
Unfished age 1+ biomass (mt)	2218.6	(1480.3-2956.8)
Unfished recruitment (R0, thousands)	3305.4	(1266.9-5343.9)
Spawning output(2016 mt)	431.6	(218.8-644.3)
Depletion (2016)	0.486	(0.3659-0.6062)
Reference points based on $SB_{40\%}$		
Proxy spawning output ($B_{40\%}$)	355.2	(247.1-463.3)
SPR resulting in $B_{40\%}$ ($SPR_{B40\%}$)	0.4589	(0.4589-0.4589)
Exploitation rate resulting in $B_{40\%}$	0.1933	(0.1602-0.2264)
Yield with $SPR_{B40\%}$ at $B_{40\%}$ (mt)	218.4	(116.2-320.6)
Reference points based on SPR proxy for MSY		
Spawning output	395.7	(275.3-516)

¹²⁹ **Research And Data Needs**

research-and-data-needs

¹³⁰ We recommend the following research be conducted before the next assessment:

¹³¹ 1. List item No. 1 in the list

¹³² 2. List item No. 2 in the list, etc.

₁₃₃ **1 Introduction**

introduction

₁₃₄ **1.1 Basic Information and Life History**

basic-information-and-life-history

₁₃₅ California scorpionfish (*Scorpaena guttata*), also known locally as sculpin or spotted scorpionfish, originates from the Greek word for scorpionfishes and *guttata* is Latin for speckled. ₁₃₆ ₁₃₇ California scorpionfish is a medium-bodied fish and like other species in the genus *Scorpaena*, ₁₃₈ it produces a toxin in its dorsal, anal, and pectoral fin spines, which produces intense, painful ₁₃₉ wounds (Love et al. 1987). Scorpionfish are very resistant to hooking mortality and have ₁₄₀ shown survival under extreme conditions.

₁₄₁ Its range extends from central California (Santa Cruz) to the Gulf of California, although ₁₄₂ within U.S. waters they are most common in the Southern California Bight (Eschmeyer et al. ₁₄₃ 1983, Love et al. 1987). The species generally inhabits rocky reefs, caves and crevices, but in ₁₄₄ certain areas and seasons it aggregates over sandy or muddy substrate (Frey 1971, Love et ₁₄₅ al. 1987). California scorpionfish have been observed from the intertidal to 600 ft with a ₁₄₆ preferred depth range from 20-450 ft. Little is known about the aggregating behaviors of ₁₄₇ California scorpionfish. Marine Applied Research and Exploration (MARE) has observed ₁₄₈ California scorpionfish aggregations during the spawning season (June 2014) and also in ₁₄₉ the late fall (November 2012) from video transects in southern California. The November ₁₅₀ spawning aggregation was observed at a small rocky feature near La Jolla and the June ₁₅₁ aggregation was at a sandy area adjacent to the Farnsworth MPAs.

₁₅₂ Males and females show different growth rates, with females growing to a larger size than ₁₅₃ males, and the sexes exhibit different length-weight relationships (Love et al. 1987). Few ₁₅₄ California scorpionfish are mature at one year old (14 cm total length). Fifty-percent of fish ₁₅₅ mature at 17-18 cm (2 years old) and all by 22 cm (4 years old) (Love et al. 1987).

₁₅₆ California scorpionfish feed on a wide variety of mobile prey, including crabs, fishes (e.g., ₁₅₇ include northern anchovy, spotted cusk-eel), octopi, isopods and shrimp, (Taylor 1963, Quast ₁₅₈ 1968, Turner et al. 1969, Love et al. 1987). The species is nocturnal, but have been observed ₁₅₉ feeding during the day. Predation on scorpionfish is believed to be low, but one individual ₁₆₀ was found in the gut of a leopard shark (Love pers comm.).

₁₆₁ **1.2 Early Life History**

early-life-history

₁₆₂ California scorpionfish utilize the “explosive breeding assemblage” reproductive mode in ₁₆₃ which fish migrate to, and aggregate at traditional spawning sites for brief periods (Love ₁₆₄ et al. 1987). California scorpionfish migrate to deeper waters (120-360 ft) to spawn during ₁₆₅ May-August, with peak spawning occurring July. The species is oviparous, producing floating, ₁₆₆ gelatinous egg masses in which the eggs are embedded in a single layer (Orton 1955) and it is

¹⁶⁷ believed that spawning takes place just before, and perhaps after dawn, in the water column
¹⁶⁸ (Love et al. 1987). The same study tagged California scorpionfish and suggests individuals
¹⁶⁹ return to the same spawning site, but information is not available on non-spawning season
¹⁷⁰ site fidelity.

¹⁷¹ Little is known about California scorpionfish larvae. The CalCOFI survey observed 463
¹⁷² California scorpionfish larvae from 1977-2000, with the majority at station close to Oxnard
¹⁷³ (east of the Channel Islands) (Moser et al. 2002). Higher densities of larvae have been
¹⁷⁴ observed in the CalCOFI stations throughout Baja, peaking south of Punta Eugenia from
¹⁷⁵ July to September. The hatching length is reported as 1.9-2.0 mm (Washington et al. 1984)
¹⁷⁶ and transformation length of greater than 1.3 cm (Washington et al. 1984) less than 2.1 cm
¹⁷⁷ (Moser 1996).

¹⁷⁸ 1.3 Map

map

¹⁷⁹ A map showing the scope of the assessment and depicting boundaries for fisheries or data
¹⁸⁰ collection strata is provided in Figure 1.

¹⁸¹ 1.4 Ecosystem Considerations

ecosystem-considerations-1

¹⁸² In this assessment, ecosystem considerations were not explicitly included in the analysis.
¹⁸³ This is primarily due to a lack of relevant data and results of analyses (conducted elsewhere)
¹⁸⁴ that could contribute ecosystem-related quantitative information for the assessment.

¹⁸⁵ 1.5 Fishery Information

fishery-information

¹⁸⁶ The hook-and-line fishery off California developed in the late 19th century (Love et al.
¹⁸⁷ 2002).

¹⁸⁸ The rockfish trawl fishery was established in the early 1940s, when the United States became
¹⁸⁹ involved in World War II and wartime shortage of red meat created an increased demand for
¹⁹⁰ other sources of protein (Harry and Morgan 1961, Alverson et al. 1964).

¹⁹¹ California scorpionfish comprise a minor part of the Californian sport and commercial fisheries
¹⁹² (Love et al. 1987). Historically, California scorpionfish were taken commercially by hook and
¹⁹³ line and, occasionally, by round haul nets (Daugherty 1949). Scorpionfish were commonly
¹⁹⁴ caught around Santa Catalina Island during the late 19th Century with gillnets (Jordan
¹⁹⁵ 1887). The 1937 Bureau of Commercial Fisheries report noted that California scorpionfish
¹⁹⁶ had been a fairly important commercial species for a long time. The species was targeted by
¹⁹⁷ a few fishermen during the summer months, and was also taken as a bycatch in the rockfish

198 fisheries. By 1949, Bureau of Marine Fisheries reported
199 “[Scorpionfish] will even come to the surface to lights at night” and were also taken in round
200 haul nets. At that time, scorpionfish were rarely targeted by fishermen except by a few
201 specialists.

202 More recently, commercial bottom longlines have been used to target spawning aggregations
203 offshore of Long Beach (Love et al. 1987). Since the early 1990s, trawl catch has been
204 a substantial component of the commercial catch. Commercial landings have fluctuated
205 substantially over time, which could, in part, be due to changes in targeting and El Nio
206 events (Love et al. 1987). A high proportion of the catch landed in California during the
207 1960s and 1970s was taken from Mexican waters. In recent years, most of the catch has come
208 from around the Los Angeles region. In general, the majority of the commercial catch has
209 come from the Los Angeles region, except in the 1960s and 1970s when the majority of the
210 catch came from the San Diego region and Mexican waters.

211 California scorpionfish is not a major target in the recreational fishery. They are most
212 often taken by boat fishermen, but fairly large numbers are caught from piers, jettys, and
213 rocky shorelines. The Commercial Passenger Fishing Vessel (CPFV; also referred to as
214 the recreational party/charter or PC mode) effort has remained relatively constant over
215 a long period (1959-1998) (Dotson and Charter 2003). However, there appears to be a
216 shift in effort towards less utilized species, such as California scorpionfish, over the past
217 decade (Dotson and Charter 2003). Especially as catch limits for rockfish have become
218 more restricted commercial passenger fishing vessels (CPFV) operators target California
219 scorpionfish spawning aggregations during spring and summer (Love et al. 1987), and also
220 target California scorpionfish in the winter when other fisheries are closed.

221 California scorpionfish become a target species for day boats during the spawning months
222 when spawning aggregations can be located. There are a small number of boats that specialize
223 in targeting these aggregations. The spawning aggregations occur in deeper waters, often
224 times outside of the three nautical mile state jurisdiction. It is also unknown what fraction
225 of the population aggregates during the spawning season, e.g., all mature fish.

226 Aggregate mortality has been far below the Annual Catch Limits (ACL) established by the
227 2005 stock assessment. The ACL projections from the 2005 assessment assumed that the
228 entire ACL was being taken each year and as a result, the ACL for each subsequent year
229 declined despite under-attainment in reality.

230 In addition, in 2014, recreational catch was higher than expected. As a result, in 2014, the
231 combined recreational and commercial catch exceeded the OFL by 2mt (1%) resulting from
232 assumption that the ACL had been attained. Subsequently, action was taken to decrease the
233 recreational season by four months (September 1 - December 31). A catch only update of
234 the stock was undertaken in 2015 (Wallace and Budrick 2015) that imputed the actual catch
235 values since the last assessment, resulting in significant increase in the OFL and ACL.

236 Retrospectively, the catch in 2014 was well below the OFL as well as the ACL that would
237 have been in place had the ACL values from the actual attainment been in place in 2014.
238 Thus the stock has not been subject to overfishing since the original assessment or been in
239 an overfished condition historically and is considered healthy.

²⁴⁰ The season restriction in the recreational fishery remained in place as a precautionary measure
²⁴¹ until the full assessment is completed to better inform the current status of the stock, catch
²⁴² limits and regulations given the perspective provided.

²⁴³ 1.6 Summary of Management History

[summary-of-management-history](#)

²⁴⁴ Prior to the adoption of the Pacific Coast Groundfish Fishery Management Plan (FMP) in
²⁴⁵ 1982, California scorpionfish (*Scorpaena guttata*) was managed through a regulatory process
²⁴⁶ that included the California Department of Fish and Wildlife (CDFW) along with either
²⁴⁷ the California State Legislature or the Fish and Game Commission (FGC) depending on
²⁴⁸ the sector (recreation or commercial) and fishery. With implementation of the Pacific Coast
²⁴⁹ Groundfish FMP, California scorpionfish came under the management authority of the Pacific
²⁵⁰ Fishery Management Council (PFMC), being incorporated, along with all genera and species
²⁵¹ of the family Scorpidae, into a federal rockfish classification and managed as part of
²⁵² “Remaining Rockfish” under the larger heading of “Other Rockfish” (PFMC (2002, 2004),
²⁵³ Tables 31-39).

²⁵⁴ The ABCs provided by the PFMC’s Groundfish Management Team (GMT) in the 1980’s were
²⁵⁵ based on an analysis of commercial landings from the 1960’s and 1970’s. For this analysis,
²⁵⁶ most of the rockfishes were lumped into one large group. This analysis indicated that the
²⁵⁷ landings for rockfish in the Monterey-Conception area were at or near ABC levels (Pacific
²⁵⁸ Fishery Management Council 1993). To keep landings within these adopted harvest targets,
²⁵⁹ the Pacific Coast Groundfish FMP provided the Council with a variety of management tools
²⁶⁰ including area closures, season closures, gear restrictions, and, for the commercial sector,
²⁶¹ cumulative limits (generally for two-month periods). With the implementation of a federal
²⁶² groundfish restricted access program in 1994, allocations of total catch and cumulative limits
²⁶³ began to be specifically set for open access (including most of California’s commercial fisheries
²⁶⁴ that target California scorpionfish in Southern California) and limited entry fisheries (Pacific
²⁶⁵ Fishery Management Council 2002, 2004). As a result, in the later 1990’s as commercial
²⁶⁶ landings decreased and recreational harvest became a greater proportion of the available
²⁶⁷ harvest.

²⁶⁸ Beginning in 1997, California scorpionfish was managed as part of the *Sebastodes* complex-
²⁶⁹ south, Other Rockfish category. (*Sebastodes* complex-south included the Eureka, Monterey,
²⁷⁰ and Conception areas while *Sebastodes* complex-north included the Vancouver and Columbia
²⁷¹ areas.) The PFMC’s rockfish management structure changed significantly in 2000 with the
²⁷² replacement of the *Sebastodes* complex -north and -south areas with Minor Rockfish North
²⁷³ (now covering the Vancouver, Columbia, and Eureka areas) and Minor Rockfish South (now
²⁷⁴ Monterey and Conception areas only). The OY for these two groups (which continued to be
²⁷⁵ calculated as 0.50 of the ABC) was further divided (between north and south of 40°10' N.
²⁷⁶ latitude) into nearshore, shelf, and slope rockfish categories with allocations set for Limited
²⁷⁷ Entry and Open Access fisheries within each of these three categories (January 4, 2000, 65
²⁷⁸ FR 221; PFMC (2002), Tables 54-55). Because of its depth range and southern distribution,

²⁷⁹ California scorpionfish was included within the Minor Rockfish South, Other Rockfish ABC
²⁸⁰ and managed under the south of 40°10' N. latitude nearshore rockfish OY and trip limits
²⁸¹ (PFMC (2002), Table 29).

²⁸² Along with the above changes, in 2000 the southern area divided into two separate management
²⁸³ areas at Point Lopez, 36°00' N. latitude. This was followed in 2001 with the implementation
²⁸⁴ of the northern rockfish and lingcod management area between (40°10' N. latitude) and Point
²⁸⁵ Conception (34°27' N. latitude); and the southern rockfish and lingcod management area
²⁸⁶ between Point Conception and the U.S.- Mexico border. These were later revised starting
²⁸⁷ in 2004 with the northern rockfish and lingcod management area redefined as ocean waters
²⁸⁸ from the Oregon-California border (42°00' N. latitude) to 40°10' N. latitude, the central
²⁸⁹ rockfish and lingcod management area defined as ocean waters from 40°10' N. latitude to
²⁹⁰ Point Conception, and the southern rockfish and management area continuing to be defined
²⁹¹ as ocean waters from Point Conception to the U.S.-Mexico border.

²⁹² Cowcod Conservation Areas (CCAs) also were established in 2001 to reduce fishing effort
²⁹³ in areas with high encounter rates of cowcod rockfish (PFMC (2002), Table 29). These
²⁹⁴ areas were closed to all recreational and commercial fishing for groundfish except for minor
²⁹⁵ nearshore rockfish1 (including California scorpionfish) within waters less than 20 fathoms.
²⁹⁶ The California Rockfish Conservation Area (CRCA) was defined as those ocean waters south
²⁹⁷ 40°10' N. latitude to the U.S.-Mexico border with different depth zones specified for the areas
²⁹⁸ north and south of Pt. Reyes (37°59.73' N. latitude).

²⁹⁹ During the late 1990's and early 2000's, major changes also occurred in the way that California
³⁰⁰ managed its nearshore fishery. The Marine Life Management Act (MLMA), which was passed
³⁰¹ in 1998 by the California Legislature and enacted in 1999, required that the FGC adopt
³⁰² an FMP for nearshore finfish. It also gave authority to the FGC to regulate commercial
³⁰³ and recreational nearshore fisheries through FMPs and provided broad authority to adopt
³⁰⁴ regulations for the nearshore fishery during the time prior to adoption of the nearshore finfish
³⁰⁵ FMP. Within this legislation, the Legislature also included commercial size limits for nine
³⁰⁶ nearshore species including California scorpionfish (10-inch minimum size) and a requirement
³⁰⁷ that commercial fishermen landing these nine nearshore species possess a nearshore permit.

³⁰⁸ Following adoption of the Nearshore FMP and accompanying regulations by the FGC in fall
³⁰⁹ of 2002, the FGC adopted regulations in November 2002 which established a set of marine
³¹⁰ reserves around the Channel Islands in Southern California (which became effective April
³¹¹ 2003). The FGC also adopted a nearshore restricted access program in December 2002 (which
³¹² included the establishment of a Deeper Nearshore Permit) to be effective starting in the 2003
³¹³ fishing year.

³¹⁴ Although the Nearshore FMP provided for the management of the nearshore rockfish and
³¹⁵ California scorpionfish, management authority for these species continued to reside with
³¹⁶ the Council. Even so, for the 2003 and subsequent fishery seasons, the State provided
³¹⁷ recommendations to the Council specific to the nearshore species that followed the directives
³¹⁸ set out in the Nearshore FMP. These recommendations, which the Council incorporated into

³¹⁹ the 2003 management specifications, included a recalculated OY for Minor Rockfish South
³²⁰ - Nearshore, division of the Minor Rockfish South - Nearshore into three groups (shallow
³²¹ nearshore rockfish; deeper nearshore rockfish; and California scorpionfish), and specific harvest
³²² targets and recreational and commercial allocations for each of these groups.

³²³ Also, since the enactment of the MLMA, the Council and State in a coordinated effort
³²⁴ developed and adopted various management specifications to keep harvest within the harvest
³²⁵ targets, including seasonal and area closures (e.g. the CCAs; a closure of Cordell Banks
³²⁶ to specific fishing), depth restrictions, minimum size limits, and bag limits to regulate the
³²⁷ recreational fishery and license and permit regulations, finfish trap permits, gear restrictions,
³²⁸ seasonal and area closures (e.g. the RCAs and CCAs; a closure of Cordell Banks to specific
³²⁹ fishing), depth restrictions, trip limits, and minimum size imits to regulate the commercial
³³⁰ fishery.

³³¹ 1.7 Management Performance

management-performance-1

³³² Management performance table: (Table [f](#))

³³³ A summary of these values as well as other base case summary results can be found in Table
³³⁴ [i](#).

³³⁵ 1.8 Fisheries off Mexico

fisheries-off-mexico

³³⁶ The California scorpionfish's range extends into to Abreojos, Baja California.

³³⁷ The species is also found in the northern Gulf of California and Guadalupe Island. No formal
³³⁸ stock assessments have been conducted for California scorpionfish in Mexican waters.

³³⁹ 2 Assessment

assessment

³⁴⁰ 2.1 Data

data

³⁴¹ Data used in the California scorpionfish assessment are summarized in Figure [2](#).

³⁴² A description of each data source is below.

³⁴³ 2.1.1 Commercial Fishery Landings

commercial-fishery-landings

³⁴⁴ Commercial catches of California scorpionfish (often landed as "sculpin") are available back
³⁴⁵ to 1916. Landings from 1916 to 1935 are presented in CDFG Fish Bulletin No. 49 and

³⁴⁶ Bulletin No. 149 provides tabulated data from 1916 to 1968. Over 99% of the commercial
³⁴⁷ catches of California scorpionfish are from south of Pt. Conception.

³⁴⁸ Whenever possible, catches from north of Pt. Conception and also caught in Mexico but
³⁴⁹ landed in the U.S. were excluded from the commercial catch histories.

³⁵⁰ [California Explores the Ocean](#)(CEO) provides landings data taken from the CDFG Fish
³⁵¹ Bulletins in electronic form, as well as electronic copies of all CDFG Fish Bulletins.

³⁵² Statewide annual landings are available for California scorpionfish from 1916 to 1925, and
³⁵³ are assumed to be taken by hook-and-line. Data by area and month are given in a series of
³⁵⁴ bulletins, each bulletin usually providing information for a single year. Data by region and
³⁵⁵ month is available for 1926 to 1986. The Santa Barbara region includes San Luis Obispo,
³⁵⁶ Santa Barbara and Ventura counties. Catches from this region were included in the catch
³⁵⁷ history and comprised less than 10 mt for the period from 1926-1968 (the period when data
³⁵⁸ at the regional scale are available).

³⁵⁹ Catches from Mexico can be separated from the total catch starting in 1931, although the
³⁶⁰ CDFG Bulletins do not report catches originating from Mexican waters available for all years,
³⁶¹ e.g., 1932-1934. It is assumed that before 1931 there was no catch taken from Mexican waters
³⁶² landed in California.

³⁶³ The [CALCOM](#) database was queried (March 7, 2017) for commercial landing estimates of
³⁶⁴ California scorpionfish in California, 1969-2016. Landings were stratified by year, quarter,
³⁶⁵ live/dead, market category, gear group, port complex, and source of species composition
³⁶⁶ data (actual port samples, borrowed samples, or assumed nominal market category). All
³⁶⁷ CALCOM California scorpionfish landing data are either actual port samples or the nominal
³⁶⁸ California scorpionfish market category. However, catches in CALCOM do not separate out
³⁶⁹ catches originating from Mexican waters and landed at U.S. ports.

³⁷⁰ The Commercial Fisheries Information System (CFIS; maintained by CDFW) contains
³⁷¹ California catch in pounds by gear and port for 1969 to 2016 (Figures). The CFIS data come
³⁷² from landing receipts or “fish tickets” filled out by the markets or fish buyers as required by
³⁷³ the state for all commercial landings. The fish tickets include the CDFW block in which the
³⁷⁴ majority of the landings were caught.

³⁷⁵ Landings with a block solely in Mexican waters (blocks >900) were removed from the catch
³⁷⁶ history. Landings with reported blocks 877-882 with area in both U.S. and Mexican waters
³⁷⁷ were retained in the catch histories. The commercial catch is dominated by the hook-and-line
³⁷⁸ fishery (89% of total catches).

³⁷⁹ The catch by reported gear types: hook-and-line, fish pot, trawl, gill net, and other can be
³⁸⁰ found in Table 1. Catch taken by fish pot and other gears is added to the hook-and-line
³⁸¹ catch in the stock assessment (30.6 mt from fish pot and 93.9 mt from other gears).

³⁸² In the assessment, catch for 1916 to 1968 is taken from the CDFG Fish Bulletins. Catch by
³⁸³ gear for 1969 to 2004 is taken from CFIS.

384 **2.1.2 Commercial Discards**

commercial-discards

385 Information on commercial discards from the West Coast Groundfish Observer Program
386 (WCGOP) are available starting in 2004. The commercial fishery for California scorpionfish
387 has been minimal since the early 2003 (averaging 3.5 mt per year). The available length
388 composition data from the observed discards is minimal, with 151 fish measured from 2004-
389 2015, and less than half a metric ton. Given the discard mortality of only 7%, and the small
390 total catches in the recent years, discards from the commercial fleet are not considered in the
391 assessment.

392 **2.2 Commercial Fishery Length And Age Data**

commercial-fishery-length-and-age-data

393 Biological data from commercial fisheries that caught California scorpionfish were extracted
394 from CALCOM on March 7, 2017. Samples from the hook and line fishery were available
395 from 1999 (1 trip) and 2013-2015 (1 trip per year), and for 1999 (1 trip) and 2006 (2 trips)
396 from the trawl fishery. A total of 87 fish were measured and length compositions were based
397 on expanded catch-weighted landings. The samples from 1999 for both fisheries were replaced
398 by samples from the market category study described below.

399 The CDFW conducted a market study from 1990-2004 in southern California (Laughlin
400 and Ugoretz 1998) to monitor and summarize local commercial catches. The ports sampled
401 included San Diego, Santa Barbara/Ventura and Long Beach/San Pedro. Very few of the
402 samples from Santa Barbara and San Diego (4 samples each from the hook-and-line and
403 trawl fisheries Santa Barbara, and 1 sample from the hook-and-line fishery in San Diego)
404 reported California scorpionfish, and are excluded from the length composition data.

405 Length composition for California scorpionfish are available from the Long Beach samples for
406 the hook-and-line (Table 2), gillnet (Table 3), and trawl fisheries (Table 4). Length samples
407 from both groundfish (otter) trawls and single-rigged shrimp trawls were available from the
408 market study. The average size of fish from the otter trawls (26.5 cm) was smaller than from
409 the shrimp trawl samples (28.1 cm). Over 70% of California scorpionfish catch from the
410 trawl sector was landed from single-rigged shrimp trawls, which best represent the length
411 composition of the trawl fleet (CALCOM).

412 The input sample sizes were calculated via the Stewart Method (Ian Stewart, personal
413 communication, IPHC):

414 $\text{Input effN} = N_{\text{trips}} + 0.138 * N_{\text{fish}}$ if $N_{\text{fish}}/N_{\text{trips}}$ is < 44

415 $\text{Input effN} = 7.06 * N_{\text{trips}}$ if $N_{\text{fish}}/N_{\text{trips}}$ is ≥ 44

416 **2.2.1 Sport Fishery Removals and Discards**

sport-fishery-removals-and-discards

417 Data used in reconstructing the retained catch and discarded mortality for California scor-
418 pionfish in the California recreational fishery are from the Commercial Passenger Fishing
419 Vessel (CPFV) Logbooks (1932-2017), the Marine Recreational Fishery Statistical Survey
420 (MRFSS, 1980-2003) and the California Recreational Fishery Survey (CRFS, 2004-2017).
421 Total catch was accounted for including retained catch as well as the estimate of fish dis-
422 carded dead assuming a 7% discard mortality rate approved for use in management in the
423 regulatory specifications for 2009-2010 (Pacific Fishery Management Council 2008). The
424 MRFSS and CRFS data provide estimates of mortality for four fishing “modes” including
425 the Party/Charter Boat, Private/Rental Boat, Man Made (piers and jetties etc.) and Beach
426 and Bank modes.

427 While estimates of mortality from the Party/Charter (PC) boat mode is available from the
428 MRFSS and CRFS surveys for the Party/Charter Boat mode for 1980-2017, estimates from
429 the CRFS data from 2011-2017 and data from CPFV Logbook for 1932-2010 were used to
430 represent catch from this mode. The Party/Charter Phone Survey was used to estimate
431 effort used in producing effort estimates for CRFS between 2004 and 2010, which was subject
432 to negative bias due to the low of participation in the survey south of Point Conception.
433 The Coastal County Household Telephone Survey was used to estimate fishing effort for
434 the MRFSS survey from 1980-2003 and was subject to potential positive avidity bias in
435 participation by those contacted by the survey. As a result, the CPFV logbooks provided the
436 reported number of retained and discarded California scorpionfish used to estimate mortality
437 from 1932-2010.

438 This is consistent with the catch based update conducted in 2015 as well as the original
439 assessment, both of which used estimates of catch from logbooks to represent catch in the
440 PC mode with the exception of the years after 2011 when effort estimates used in CRFS
441 estimates were derived from logbooks.

442 An under-reporting adjustment reflecting an average 20% of logs not being submitted was
443 applied to all estimates for the PC mode from 1932-2010. Annual average weights from this
444 mode for retained catch from the MRFSS or CRFS estimates for 1980-2010 and average
445 weight from 1980-1984 was applied to the preceding years. To estimate discard mortality
446 for the PC mode, the annual average weight was applied in respective years from lengths
447 collected sampling onboard CPFVs by the CRFS survey for 2004-2010 were applied to the
448 number of discards from the CPFV logbooks and the average weight over this entire period
449 were applied to the preceding years for 1995-2003. For the period between 1980 and 1994,
450 the MRFSS estimates for discards were used to reflect discarding due to the paucity of data
451 on the number of discards from PC logbooks prior to 1995.

452 For all other modes, the MRFSS (1980-2003) and CRFS (2004-2017) based estimates of
453 retained catch and discard mortality were used. There was a lapse in MRFSS sampling from
454 1990 through 1992, for which retained catch and discard mortality were estimated using the
455 average of values three years before and three years after the lapse for all modes other than

456 the PC mode. For the PC mode, estimates of numbers of fish were available from logbook
457 data and average weight from the three years before and after this period were applied to
458 provide estimates for the PC mode.

459 Estimates of retained catch and discards were not available from the non-PC modes prior
460 to 1980, thus the ratio of catch in the PC mode to the other modes for 1980 through 1985
461 was used to provide an estimate of catch in the other modes in the years 1932-1979. In the
462 case of the PR mode, a linear ramp in the ratio adjustment between PC and PR modes was
463 applied between 1966 and 1979 from 0.55 in 1980 to 0.10 in 1965, reflecting the increase in
464 the relative proportion of catch contributed by the PR mode with time as more individuals
465 anglers purchased vessels, as recommended in the California Catch Reconstruction (Ralston
466 et al. 2010), and the ratio of 0.10 was assumed for all years prior. The ratio of PC estimates
467 to the MM and BB modes was assumed to constant and the average between 1980 and 1989
468 was applied from 1932 to 1979. Catch estimates from CPFV logbooks were not available
469 during the World War II era from 1941 until 1946 and catch was assumed to be zero for all
470 modes during this period. Estimates for retained catch and discarded mortality for 1935 to
471 1928 were estimated using a linear ramp from the value for 1928 to zero in 1936 for the PC
472 mode and ratios PC compared to other modes were used to proxy estimates for other modes
473 based on the resulting ramped values for the PC mode. The final time series of landings and
474 discard mortality are in Table 5.

475 Biological samples from the recreational fleets are desired in the sections below.

476 2.2.2 Fishery-dependent Data Sources

fishery-dependent-data-sources

477 CRFS Private Boat Dockside Intercept Survey

478 The CDFW provided the CRFS private boat dockside sampling fisheries data from 2004
479 to 2016. The data went through several data quality checks to identify the best subset of
480 available data that are consistent over the time series and provide a representative relative
481 index of abundance once standardized. The dockside sampling of the private mode (PR mode
482 in RecFIN) consists of samples from a primary series of ports (PR1) where the majority
483 of fishing effort for this mode originates and a secondary series of ports with historically
484 low effort (PR2). Only PR1 samples were used for this index as the sampling forms for
485 the PR2 index have changed over time and the data could not reliably be collapsed to the
486 trip level. The dockside data consist of two types of data; Type 2 data contain records of
487 angler-reported catch, i.e., catch that was not observed by the sampler and Type 3 data
488 includes sampler-examined retained catch. Of the Type 2 reported catch for scorpionfish, less
489 than one percent were reported “thrown back dead” and five percent reported as retained
490 to eat. Given that the reported retained catch is a small fraction of the catch overall and
491 discard mortality of California scorpionfish is low, only the Type 3 examined catch are used
492 in the index.

493 The survey records the number of contributing anglers (number of anglers on the vessel for
494 the private mode), but does not contain data on hours fished. For this index, angler-day
495 was the assumed effort. The data were filtered to trips fishing with hook-and-line gear in
496 southern California. Trips with a primary fishing area of Mexico were also removed. The
497 CRFS dockside private boat records with these broad filters include 44,128 trips of which
498 3,802 caught California scorpionfish (8.6%).

499 The Stephens-MacCall approach was used to identify trips with a high probability of catching
500 California scorpionfish (Stephens and MacCall 2004). Prior to using the Stephens-MacCall
501 approach to select relevant trips a number of other filters were applied to the data to minimize
502 variability in CPUE estimates. Over the course of the time series only 45 trips from Santa
503 Barbara county encountered California scorpionfish, ranging from 0-10 trips a year. The
504 Stephens-MacCall approach was applied with and without trips from Santa Barbara and the
505 same species were identified as indicators and counter-indicators. For the final model prior to
506 Stephens-MacCall, trips from Santa Barbara were excluded, leaving 41,235 trips, and 3,747
507 of those caught California scorpionfish (Table 6).

508 Coefficients from the Stephens-MacCall analysis (a binomial GLM) are positive for species
509 which co-occur with California scorpionfish, and negative for species that are not caught with
510 California scorpionfish (Figure 4). Potentially informative species for the Stephens-MacCall
511 analysis were limited to species caught in at least one percent of all trips and caught in at
512 least five years. Some of these never occurred with California scorpionfish (strong ‘counter-
513 indicators’) and records with these species were removed from the data prior to estimation
514 of the index. Strong counter-indicators for the CRFS private boat index included yellowfin
515 tuna and dolphinfish.

516 A total of 8,590 trips were retained following the Stephens-MacCall filter, with 3,056 all
517 positive California scorpionfish trips retained. The California scorpionfish recreational fishery
518 in the southern management area was closed for eight months in 2004 and nine months in
519 2005. The majority of records from 2004 and 2005 are from the period when the fishery
520 was closed and were removed from the analysis (Figure 3). Records from months with the
521 fishery was closed from 2006-2016 were also excluded from the index since this index relies
522 on sampler-examined retained catch.

523 Catch per unit effort was modeled using a delta-GLM approach, where the catch occurrence
524 (binomial) component was modeled using a logit link function and the positive catch compo-
525 nent was modeled after log-transformation of the response variable, according to a normal
526 distribution with an identity link function. The units for CPUE are fish landed/anglers. A
527 gamma distribution for the positive catch component was also explored, but model selection
528 favored the lognormal model. The raw CPUE of factors considered in the model by year are
529 shown in Figure 5.

530 Model selection procedures selected the covariates *2-month wave* and *county* as important
531 for both the catch occurrence and positive catch component models for all data sets, along
532 with the categorical year factor used for the index of abundance (Table 7).

533 The Q-Q goodness of fit plot for the lognormal portion of the model shows a moderate fit to
534 the data (Figure 6). final index indicates a decrease in relative abundance from 2006 to 2010,
535 at which point the index is relatively flat (Figure 7).

536 Biological samples from trips retaining California scorpionfish were collected during the
537 dockside surveys. Lengths of California scorpionfish from 1980-2016 for the private mode
538 were provided by RecFIN by Edward Hibsch (PSMFC) on November 29, 2016. Length
539 measurements from the private mode were provided directly from CDFW for the years
540 2004-2016 Table 9. The number of trips is the number of unique ID_CODEs from RecFIN for
541 1980-2003. Starting in 2004 with the CRFS program, the number of unique trips sampled in
542 the private boat mode was recorded. The recreational private fleet tends to select larger fish
543 than the recreational party/charter fleet, which is one reason the private and party/charter
544 fleets were maintained as two separate fleets in the base model. No length data for discarded
545 fish from the recreational private mode fleet are available.

546 CRFS CPFV Logbook Index

547 CPFV operators have been required to submit written catch logs with daily trips records of
548 catches to CDFW since 1935. The logbook data from 1936-1979 are available as monthly
549 summaries, which do not contain the level of detail needed for an index of abundance. CDFW
550 provided the CPFV logbook data from 1980-2016 (Charlene Calac, CDFW). Logbook data
551 from 1980-2016 contain records for each trip, including the fishing date, port of landing,
552 vessel name and number, CDFG block area fished (Figure 1), angler effort, number of fish
553 kept and discarded by species. As of 1994, operators were required to report the number
554 of fish discarded and lost to seals. Prior to 1994, it is assumed that all reported fish were
555 retained. Details and additional information on the historical logbook database can be found
556 in Hill and Schneider (1999).

557 The number of anglers on board the vessel and the hours fished are included in the database
558 for all years. Only retained fish are included in the index of abundance the unit of effort
559 is angler hours. A number of data filters were applied to the data to account for possible
560 mis-reporting, e.g., trips reporting retained California scorpionfish in top 1% of the data
561 (>325 fish). Trips fishing outside of California scorpionfish habitat (reported as targeting
562 pelagic species) or trips reporting a block with a minimum depth deeper than 140 m were
563 also filtered out.

564 Because California scorpionfish is not a primary target species, boats with fewer than 10
565 trips retaining California scorpionfish were removed from the analysis. Data were also filtered
566 to only include catches reported from blocks South of Pt. Conception and north of the U.S.-
567 Mexico border (Figure 1), and blocks with at least 100 trips retaining California scorpionfish
568 and a total of 500 trips. A full description of the data filters is in Table 10. A total of
569 432,868 trips were retained for the index of abundance, 202,937 of which caught California
570 scorpionfish.

571 Two different area factors were considered for the standardization, block and region.
572 The 60 retained blocks were split into nearshore regions north and south of San Pedro and

573 the northern and southern islands, for four regions. Both a delta model and a negative
574 binomial model were considered for index standardization. However, due to the large number
575 of records, the traditional jackknife routine to estimate uncertainty was not possible.

576 California scorpionfish were present in 47% of all trips, and standardized with a negative
577 binomial model. Factors considered were *year*, *month*, and *area* (either block or region). A
578 model with blocks and was selected over a model with region by 39,180 AIC. The final model
579 includes *year*, *month*, and *block* with a log link and effort as an offset (Table 11).

580 The standardized index shows a cyclic pattern, with period of higher CPUE (late 1980's to
581 early 1990's and late 1990s) and has shown a general downward trend since 2008 (Figure 11).
582 An interesting note is the similarity in standardized CPUE between the CPFV logbook index
583 and the CPFV dockside index (not used in the stock assessment model) from 1992-1997 (for
584 a Stephens-MacCall threshold of 0.1) (Figure 10).

585 MRFSS Party/Charter Boat Dockside Index

586 From 1980 to 2003 the MRFSS program sampled landings at dockside (called an “intercept”)
587 upon termination of recreational fishing trips. The program was temporarily suspended
588 from 1990-1992 due to lack of funding. For purposes of this assessment, the MRFSS time
589 series is truncated at 1998 due to overlap with an alternative index used to represent 1999
590 onward using onboard sampling data making analysis using the dockside data redundant
591 (see “Recreational Onboard Observer Surveys”). Only trips south of Point Conception were
592 included in the analysis as California scorpionfish are exceedingly uncommon in the catch to
593 the north. The California party and charter boat (a.k.a. “PC mode,” commercial passenger
594 fishing vessel, or CPFV) samples used in the present analysis provide catch and effort data
595 aggregated at the trip level. Each entry in the RecFIN Type 3 database corresponds to a
596 single fish examined by a sampler at a particular survey site. Since only a subset of the catch
597 may be sampled, each record also identifies the total number of that species possessed by
598 the group of anglers being interviewed. The number of anglers and the hours fished are also
599 recorded. Unfortunately the Type 3 data do not indicate which records belong to the same
600 boat trip. Because our aim is to obtain a measure of catch per unit effort (fish per angler
601 hour), it is necessary to separate the records into individual trips. For this reason trips must
602 be inferred from the RecFIN data. This is a lengthy process, and is outlined in Supplemental
603 Materials (“Identifying Trips in RecFIN”).

604 Since recreational fishing trips target a wide variety of species, standardization of the catch
605 rates requires selecting trips that are likely to have fished in habitats containing California
606 scorpionfish. The method of Stephens and MacCall (2004) was used to identify trips with a
607 high probability of catching California scorpionfish, based on the species composition of the
608 catch in a given trip. Prior to applying the Stephens-MacCall filter, we identified potentially
609 informative “predictor” species , i.e., those with sufficient sample sizes and temporal coverage
610 (at least 30 positive trips total, distributed across at least 10 years of the index) to inform
611 the binomial model. Coefficients from the Stephens-MacCall analysis (a binomial GLM) are
612 positive for species which co-occur with California scorpionfish, and negative for species that
613 are not caught with California scorpionfish.

614 Data for dockside sampling of 6,295 commercial passenger fishing vessel (CPFV) trips south
615 of Point Conception by the Marine Recreational Fishery Statistical Survey (MRFSS) were
616 filtered using the Stephens-McCall method to identify trips with catch associated with
617 California scorpionfish and the resulting trips analyzed in a delta-GLM including year and
618 county to produce annual indices of abundance for the period 1980 through 1998 . To
619 eliminate trips targeting species caught near the surface for all or part of the trip where
620 California scorpionfish do not occur, prior applying the Stephens-MacCall filter, trips with
621 catch of bluefin tuna, yellowfin tuna, dorado, Pacific bonito, skipjack, albacore, chinook
622 salmon, coho salmon and bigeye tuna were removed. Trips with catch of yellowtail amberjack
623 were also removed since effort on such trips can often be focused in the surface and mid-water
624 where California scorpionfish do not occur. In addition, trips with aggregate effort less below
625 and above 95% percentile (less than 2 and over 109.5 hours) were removed to exclude trips
626 for which either too little effort was exerted to be informative or longer trips that may make
627 an excessive contribution to the effort likely distributed over a number of targets only some
628 of which may co-occur with California scorpionfish biasing low the resulting CPUE. Lastly,
629 trips in Santa Barbara County were removed due the low number of positive samples for
630 California scorpionfish since it resides in the northern extent of their range and this is a
631 transition zone between biogeographic provinces in which the presence of more northerly
632 distributed species could adversely affect the ability of the Stephens-MacCall filtering method
633 to identify co-occurring species. Each of these filtering steps and the resulting number of
634 trips remaining in the sampling frame are provided in Table 13.

635 Removal of the aforementioned trips resulted in a total of 3,968 trips to which the Stephens-
636 MacCall filtering method was applied. Species that composed less than 5% of the catch
637 were excluded from analysis to prevent these uncommon species from affecting correlations
638 identified using the algorithm. Chub mackerel, Pacific mackerel and barracuda were removed
639 as potential predictor species despite having weak positive correlations with California
640 scorpionfish since they are predominantly pelagic and their co-occurrence is not expected to
641 be predictive. As expected, positive indicators of California scorpionfish trips include several
642 species of nearshore rockfish, California sheephead, California halibut, Pacific sanddabs and
643 seabasses and counter-indicators include several species of deep-water rockfish (Figure 8).
644 While the filter is useful in identifying co-occurring or non-occurring species assuming all
645 effort was exerted in pursuit of a single target, the targeting of more than one target species
646 can result in co-occurrence of species in the catch that do not truly co-occur in terms of
647 habitat associations informative for an index of abundance, presenting a confounding influence
648 in selecting trips using the methods employed. Thus the filtering is intended to remove those
649 trips for which effort was targeted in deeper water than California scorpionfish commonly
650 occur.

651 Two levels of filtering were applied using the Stephens-MacCall Filter. The Stephens-MacCall
652 filtering method identified the probability of occurrence (in this case 0.27) at which the rate
653 of false positives and false negatives for the presence of California scorpionfish were equal as
654 a heuristic for selecting a threshold for trips in appropriate habitat to be included in analysis.
655 The trips from this criteria for selection was compared to an alternative method including
656 the false positive trips as well as all positive trips for California scorpionfish supported by

the assumption that if California scorpionfish were caught in such trips, they must constitute appropriate habitat justifying their inclusion. In addition, the false positives from a lower probability of occurrence (0.10) that was considered to reflect a less stringent threshold inclusive of more trips including a higher proportion of the false positive trips combined with the positive trips from the entire data set was evaluated for comparison.

Catch per angler hour (CPUE; number of fish per angler hour) was modelled using a delta model (Lo et al. 1992, Stefnsson 1996). Model selection using Akaike Information Criterion (AIC) and Bayesian Information Criteria (BIC) supported inclusion of year and region effects in both the binomial and lognormal components of the index for both the model with false positives from the 0.27 threshold and the 0.10 threshold. The addition of month effects (to allow for seasonal changes in CPUE) did not improve model fit in the lognormal model, but the full model including month, year and county was supported for the binomial model (Table 2). The difference in AIC values for the full model compared to the model with only year and county was greater for the binomial model (201.5) favoring the full model compared to the small difference for the lognormal model favoring the model with only year and county (8.3). As a result, the full model including year, county and month effects was selected for further analysis.

The resulting index values for 1989 were anomalously high compared to other years. In addition, the less stringent filter of 0.1 resulted in a higher index value than 0.27, which was antithetical to the expectation that including trips with fewer positive trips would decrease the CPUE. Further examination of the number of California scorpionfish per trip by year showed a lower number of trips for this year than others and a lower proportion of low catch trips explaining why exclusion of low catch trips through application of the 0.27 index reduced the relative magnitude of the 1989 index value relative to other years. As a result of this anomalous result and the low sample size, trips from 1989 were excluded from analysis.

The percentage of trips that caught California scorpionfish was 20.8% (828/3,968) prior to filtering with the Stephens-MacCall method, and 71.0% (828/1,167) with the filter set to 0.27 and 26.7% (828/3,099) with the filter set to 0.10, filtered data set. Residual-based model diagnostics for the positive component of the index suggest the data generally met the assumptions of the GLM (Figure 9). The resulting index is highly variable for both thresholds, with consistent peaks in 1984 and 1998 (Figure 10). Application of the 0.27 threshold holds the potential of biasing the resulting index values high by excluding false positive trips while including positive trips with equivalent probability of encountering California scorpionfish. The 0.1 threshold removes a high proportion of trips with shelf rockfish species indicative of effort exerted in deeper depths than are commonly occupied by California scorpionfish, while retaining false positive trips with equivalent probabilities of capture to true positives and thus was retained for further analysis.

The resulting jackknifed mean index values, standard error, coefficient of variation and confidence intervals for the 0.1 threshold model, excluding 1989, with year, month and county effects are provided in Table 14.

The results of the models with each of the thresholds provided similar trends seen in Figure

698 Figure 10 along with the results from the CPFV logbook index. The trends differ from those
699 resulting from the CPFV logbook index early in the time series, but both show an increase
700 in the mid to late 1990s. The PC dockside index was excluded from further analysis in the
701 model given that the CPFV logbook index represents the same sector of the fishery and
702 presumably contains data from some of the same trips, utilizes data for many thousands
703 more trips, and provides data from 1989 to 1992 omitted from the MRFSS data as a result
704 of filtering out 1989 and a lapse of sampling from 1990-1992.

705 *Party/Charter Dockside Length Measurements*

706 The retained catch for the recreational party/charter mode has been measured during the
707 dockside interviews since 1980, and also by two different onboard observer programs in
708 southern California by Collins and Crooke (n.d.) a combination of unpublished data and
709 a study by Ally et al. (1991) from 1984-1989 (Table 15). The length measurements from
710 Collins and Crooke (n.d.) are assumed to all be from retained fish.

711 Length measurements for California scorpionfish from 1980-2016 were provided from RecFIN
712 by Edward Hibscher (PSMFC) on November 29, 2016. The number of trips from 1980-2003
713 is the number of trips with observer catch of California scorpionfish as outlined in the
714 Supplemental Material (“Identifying Trips in RecFIN”). However, the algorithm used to
715 determine the number of trips has not been applied to RecFIN data past 2003. The number
716 of trips for 2004 and 2005, was taken as the ratio of the number of interviews (ID_CODE) in
717 RecFIN to the number of known trips for years with complete data. The number of individual
718 ID_CODEs was reduced by 38% for 2004 and 2005, and gives reasonable sample
719 sizes. From 2004-2016 the number of trips from which the samples were taken is known.

720 From 1985-1987 Ally et al. (1991) conducted an onboard observer program in southern
721 California, and measured both retained and discarded fish. Additional unpublished years
722 (1984, 1988-1999) from this onboard observer sampling program were provided by CDFW
723 (Paulo Serpa). From 1984-1989, the onboard observer program measured 11,892 retained
724 California scorpionfish compared to the 1,981 measurements in RecFIN. It is almost certain,
725 but cannot be verified, that some of the lengths from the onboard observer program were
726 input in RecFIN. Therefore, the onboard observer measurements from 1984-1989 are used
727 instead of those from RecFIN for these years.

728 **Onboard Observer Party/Charter Boat**

729 California implemented a statewide Onboard Observer Sampling Program in 1999, and began
730 measuring discarded fish in 2003 (Monk et al. 2014). The goal of the Onboard Observer
731 Sampling Program is to collect data including charter boat fishing locations, catch and
732 discard of observed fish by species, and lengths of discarded fish. The program samples the
733 commercial passenger fishing vessel (CPFV), i.e., charter boat or for-hire fleet and collects
734 drift-specific information at each fishing stop on an observed trip.

735 At each fishing stop recorded information includes start and end times, start and end location
736 (latitude/longitude), start and end depth, number of observed anglers (a subset of the total
737 anglers), and the catch (retained and discarded) by species of the observed anglers.

738 CDFW implemented a regulation of three hooks in 2000, which was reduced to (and remains
739 at) two hooks in 2001. CDFW also implemented a 10 inch size limit for California scorpionfish
740 in 2000. The length composition of retained in discarded California scorpionfish (both before
741 and after the minimum size restriction). Prior to 2001, there were no depth restrictions for
742 the southern California recreational fishery. Given these regulation changes, the data from
743 1999 and 2000 are excluded from the index.

744 From 2002 to 2005, the California scorpionfish fishery was closed from four to nine months of
745 the year. During these years, California scorpionfish were still encountered, but all discarded.
746 The onboard observer program provides the only available information on discards because
747 the sampler records both the retained and discarded catch at each fishing stop. The onboard
748 observer data are used to create two indices of abundance, one using only the discarded catch
749 and one using only the retained catch. The index of discarded catch is used as an index of
750 abundance for the recreational discard fleet, and the index derived from the retained catch is
751 treated a survey in the assessment model.

752 The entire dataset was filtered as one, regardless of retained or discarded, due to the fact that
753 discarding can occur for a number of reasons, e.g., angler preference, size limit, bag limit,
754 etc., and California scorpionfish are often retained and discarded on the same fishing drift.

755 Prior to any analyses, drifts with erroneous or missing data were removed from the data
756 considered for the California scorpionfish index. The locations of positive encounters (retained
757 + discarded) were mapped, using the drift starting locations. Regions of suitable habitat were
758 defined by creating detailed hulls (similar to an alpha hull) with a 0.01 decimal degree buffer
759 around a location or cluster of locations.

760 Any portion of a region that intersected with land was removed. Drifts that did not intersect
761 with one of these areas were considered structural zeroes, i.e., outside of the species habitat,
762 and not used in analyses.

763 Five areas were retained based on sample sizes, 1) nearshore area from the U.S./Mexico
764 border to Oceanside, 2) nearshore Oceanside to Newport Beach, 3) Newport Beach to Palos
765 Verdes, 4) Palos Verdes to Point Magu, and 4) drifts from Santa Cruz Island, Santa Barbara
766 and Anacapa Islands, Santa Catalina Island, and San Clemente Islands were combined.
767 Drifts encountering California scorpionfish north of Point Magu were rare (<5% positive
768 encounters).

769 Drift locations within the Cowcod Conservation Area (CCA) or in Mexican waters were also
770 filtered out of the dataset. The years 1999 and 2000 were removed from the index due to
771 changes in hook and gear regulations during those years. California adopted a 3-hook and
772 1-line regulation in 2000, which changed to 2-hooks and 1-line in 2001. California scorpionfish
773 is not a common target species for the CPFV fleet, but if often a fallback species, for trips
774 targeting seabass or rockfish. California scorpionfish are targeted more often in January
775 and February when the rockfish/cabezon/greenling complex is closed. Boat identifiers were
776 available for all trips in the onboard observer database. Approximately 1,000 drifts were
777 filtered out after accounting for boats that were identified as not encountering scorpionfish

778 (Table 16. A total of 26,733 drifts for the analysis were retained. Of these, 5,507 encountered
779 scorpionfish, with 3,249 discarding California scorpionfish and 3,867 retaining California
780 scorpionfish.

781 The drift-level effort cannot be parsed out between the retained and discarded catch.
782 The effort represents the total angler hours fished by the subset of observed anglers for a
783 particular drift, and is the same for both the discard-only and retained-only indices. Both of
784 the indices derived from this dataset were standardized using a delta modeling approach (Lo
785 et al. 1992).

786 *Onboard Obsever Discarded Catch Index*

787 Covariates considered in the full model included *year*, *area* (5 levels), *month* (12 levels), and
788 *20 m depth bins* (5 levels). All covariates were specified as categorical variables. A lognormal
789 model for the positives was selected by AIC over a gamma model (delta-AIC of 482.28).
790 Model selection for both the lognormal and binomial models retained all covariates (Table
791 17). The Q-Q plot for the positive catch lognormal model looks reasonable (Figure 12). The
792 final index shows a lower CPUE of the discards in 2001 and an increase from 2002-2005 when
793 the California scorpionfish recreational fishery was restricted by depth or closed (Table 18
794 and Figure 13). The relative CPUE of the discards decreases from 2006 to 2015.

795 *Discarded Catch Length Composition*

796 As of 2003, Onboard Observer program has taken length measurements for discarded fish.
797 The retained catch is measured during the dockside (angler intercept) surveys, and cannot
798 necessarily be matched to a trip with the discard lengths prior to 2012. Additional discarded
799 length measurements were available from both CDFW unpublished data (1984, 1988-1989)
800 and the Ally et al. (1991) onboard observer program from 1985-1987. The sample sizes of
801 measured discarded fish in the 1980s is small. The mean length of discarded fish is smaller
802 than for years when the length restriction was in place (Table 19).

803 The discard length composition reflects the California scorpionfish seasonal closures from
804 2002-2005. Anglers encountered and discarded fish greater than the size limit of 10 inches
805 during these years. When the fishery is open, anglers are most often only discarded California
806 scorpionfish that are smaller than the legal size. This also holds true for the length composition
807 of discarded California scorpionfish in the 1980s before there was a size limit.

808 *Onboard Obsever Retained Catch Index*

809 The index of relative abundance using the retained-only catch from the onboard observer
810 program is a separate survey fleet in the base model and has no lengths associated with it.
811 Covariates considered in the full model included *year*, *area* (5 levels), *month* (12 levels), and
812 *20 m depth bins* (5 levels). All covariates were specified as categorical variables. The final
813 model includes A lognormal model was selected by AIC over a gamma model for the positives
814 (delta-AIC of 534.9).Model selection for both the lognormal and binomial models retained all

815 covariates (Table 20). The Q-Q plot for the positive catch lognormal model looks reasonable
816 (Figure 15). The final index shows a lower CPUE of the retained catch from 2002 and 2003
817 (Table 21 and Figure 16). The relative CPUE of the retained catch shows a decline from
818 2007-2015, and an increase in 2016.

819 **2.2.3 Fishery-Independent Data Sources**

fishery-independent-data-sources

820 **Sanitation Districts Trawl Survey**

821 Sanitation districts that discharge into coastal waters are required to conduct trawls to monitor
822 the demersal fish community in the vicinity of the discharge sites part of their National
823 Pollutant Discharge Elimination System (NPDES) permits, issued by the Environmental
824 Protection Agency. All sanitation districts holding NPDES permits in southern California
825 were contacted for trawl data. The two northernmost districts, Goleta and the City of
826 Oxnard, provided data (via Aquatic Bioassay & Consulting Laboratories, Inc.), but California
827 scorpionfish have not been encountered in either district's trawl surveys. The four other
828 sanitation districts, Orange County, City of Los Angeles, Los Angeles County, and the City
829 of San Diego all encounter California scorpionfish and provided trawl data.

830 A description of the data provided by each sanitation district is provided. In contrast to the
831 inverse variance weighted index from the 2005 assessment, trawls from all sanitation districts
832 were combined to develop a single index of abundance.

833 *Orange County* The Orange County Sanitation District provided trawl data from 1970-
834 2015 (Jeff Armstrong, Orange County Sanitation District). The trawl net is a 7.6 m wide
835 Marinovich, semi-balloon otter trawl (2.54 cm mesh) with a 0.64 cm mesh cod-end liner.
836 Fixed stations are sampled either annually (summer) or semi-annually in the winter and
837 summer, Quarters 1 and 3 (Jan-March and July-September). From 1970-1985 Quarter 2,
838 trawl effort was based on a 10 minute tow time. As of 1985 Quarter 3, trawls were towed a
839 distance of 450 m. Tow time was no available for approximately half of the tows from 1985
840 Quarter 3 to 2016, and was imputed based on the mean tow time of the sampling station.

841 Eleven stations (T0-T6,T10-T13) sampled in at least 11 year and with California scorpionfish
842 present in at least 5% of trawls were retained for the analysis (1,490 trawls). For hauls with
843 fewer than 30 California scorpionfish, each fish was measured to the nearest mm (standard
844 length). In hauls with more than 30 California scorpionfish, they were tallied by size class
845 (nearest cm). Six hauls, all from station T3, caught more than 30 California scorpionfish.

846 *City of Los Angeles* The City of Los Angeles Sanitation District provided trawl data from
847 1986-2016 (Craig Campbell, Lost Angeles City). The City of Los Angeles follows the same
848 sampling protocols as the Southern California Bight Regional Monitoring Program trawl
849 survey. Stations within Los Angeles Harbor were excluded from the dataset. Years with
850 fewer than ten total hauls were removed from the analysis (1986, 1987, and 1992), as were

station sampled in fewer than 10 years. Ten stations (A1, A3, C1, C3, C6, C9A, D1T, Z2, Z3, Z4), total 921 hauls, were retained for the index of abundance.

Tow times were recorded starting in 1999, and assumed to be 10 minutes prior to 1999. Haul depth was missing for approximately half of the hauls, and was imputed as the mean depth of other hauls at that station. All California scorpionfish encountered were measured to the nearest cm (standard length).

Los Angeles County The Sanitation Districts of Los Angeles County provided quarterly trawl data from 1972-2016 (Shelly Walther, Sanitation Districts of Los Angeles County) and follow the same sampling protocols as the Southern California Bight Regional Monitoring Program trawl survey Stations sampled in fewer than 10 years or at 305 m where California scorpionfish were never observed were removed from the analysis. Non-standard and special study trawls were also removed, e.g., night trawl study in 1987. Hauls were based on a 10 minute tow time and that is assumed as the effort for all hauls. Twelve stations (stations at 23m, 61m, and 137m for T0, T1, T4, T5), totaling 1,848 hauls were retained after initial filtering. All California scorpionfish encountered were measured to the nearest cm (standard length).

City of San Diego The City of San Diego Sanitation District conducts trawls for two permits (Point Loma Ocean Outfall and South Bay Ocean Outfall) and provided data from 1985-2015 (Ami Latker and Robin Gartman, City of San Diego Public Utilities Department).

Stations sampled in fewer than 15 years were filtered from the dataset. Fourteen stations from the Point Loma Ocean Outfall (SD1-SD14) and five stations from the South Bay Ocean Outfall were retained (SD17-21), totaling 1,180 hauls. A tow time of 10 minutes is assumed for all trawls. All California scorpionfish encountered were measured to the nearest cm (standard length).

Sanitation Districts Index Standardization

Trawls from all sanitation districts were combined to standardize the index of relative abundance. This is in contrast to the 2005 assessment that standardized each of the sanitation district indices independently and combined them using an inverse variance weighting approach (Maunder et al. 2005). One reason for this was that the 2005 base model going into the STAR panel was five sub-models for the southern California Bight. Taking into consideration that the 2017 base model is a one-area model, all of the sanitation districts follow the same sampling protocols and the sampling design is a fixed station approach, the decision was made to develop a single index. The index was standardized using a delta-GLM approach.

The data were filtered for each sanitation district independently. The filters applied are described in the sections above and summarized in Table 22. The covariates considered for the lognormal and binomial models were *year* (47 levels), *quarter* (4 levels), and *station* (52 levels). A lognormal model for the positives was select over a gamma model by a delta AIC of 619. AIC model select was used for both the lognormal and binomial models and all three covariates were selected for both (Table ??). The standardized index shows a large spike in

relative CPUE in 1981, bounces around within a range of 0.1 to 0.25 from 1989 to 2009, and then declines until 2013 (Figure 17). The last three years of the index show an increase in relative abundance. The final standardized index and log-standard error can be found in Table 24. We did explore standardizing the indices independently. However, this results in a loss of data, as some sanitation district had low sample sizes in some years. The general trend in relative CPUE is similar across sanitation districts.

Sanitation Districts Length Composition

Each district measures every fish encountered in their survey. Orange County Sanitation District was the only program sampling in 1970 and 1971 and encountered a small number of California scorpionfish in those years (Figure 19). Los Angeles County has has encountered pulses of large numbers of California scorpionfish in 2002, 2004 and 2005. Figure 20 shows the distribution of lengths for California scorpionfish by 25 m depth bins and Sanitation District. The median length of fish from the City of Los Angeles trawls is smaller than the other two districts. However, there are only 120 in that depth bin, compared to 1,372 fish in the 50-74 m depth bin for the City of Los Angeles (Table 25).

The length composition indicates a fairly consistent size range of fish encountered in the trawl surveys, with a handful of smaller fish in 2016 (Figure 21). Length measurements from all 5,525 hauls of the sanitation districts were combined across sanitation districts. The number of California scorpionfish was slowest during the first few years of the time series, and also declines starting in 2012 (Table 26).

NWFSC Trawl Survey Index

The Northwest Fishery Science Center has conducted combined shelf and slope trawl surveys (hereafter referred as NWFSC trawl survey) since 2003, based on a random-grid design from depths of 55 to 1280 meters. Additional details on this survey and design are available in the abundance and distribution reports by Keller et al. (2008). Spatial locations of raw catch rates (in log scale) are shown in Figure 23.

The proportions of positive catch haul and the raw catch rates of positive hauls by depth and latitude are shown in Figure 23 and Figure 24, respectively. These figures show that more scorpionfish were caught at shallow depth zones and in the southern latitude zones. Box plots of length summary data by depth and sex (Figure 26) and by latitude and sex (Figure 26) show no evidences of different spatial distributions (by depth and latitude) by length or by sex.

The numbers of total hauls and percentages of positive catch hauls by depth and latitude zones are presented in Tables 27 and 28, respectively. Summaries of raw catch data by year are listed in Table 29. Overall, catches of scorpionfish by the survey were very low with less than 1mt fish caught during the entire 14 years of the survey. Bubble plots of length frequency distribution by year and sex are presented in Figure 27.

Summaries of age data by year and sex are presented in Table 30. There were more males (n = 529) being aged than females (n = 340), presumably indicating that there are more males

than females in the populations. The table also shows that mean ages and mean lengths for both sexes decreased in recent years. Table 31 show five percentiles of fish aged by sex, indicating more older males in the population. All aged data from the survey were used as conditional age-at-length matrix in the assessment model. The mean age-at-length indicates males and females to have similar growth patterns until around age three, at which time, females are larger than males (Table 32).

Total biomass estimates from the survey were analyzed using the VAST program (Thorson and Barnett 2017). The Q-Q goodness of fit plot and time series of total biomass estimates are shown in Figures 28 and 29, respectively. The Q-Q plots shows generally good fits and the time series of biomass estimates indicates no significant trend with relatively large uncertainties from the survey. The final survey index and log standard error used in the assessment model are in Table 33.

CSUN/VRG Gillnet Survey Index

California State University Northridge with Vantuna Research Group (CSUN/VRG) conducted a gillnet survey from 1995-2008 (Daniel Pondela, VRG). Sites along the coast from Santa Barbara to Newport were consistently sampled for the time series, as well as Catalina Island. Gillnet sets from within Marina Del Rey and Catalina Harbor were removed from the analysis.

All gillnets were the same length with six-25' panels (150' in length). The standard sampling gillnet had 1“, 1.5”, 2 square mesh, with each mesh on two panels. Samples were excluded if they were collected using a net other than the standard sampling gear. Other data filters included remove months that were not consistently sampled (Table 34).

Five covariates were considered in the model standardization, *year* (14 levels), *month* (8 levels), *site* (8 levels indicating the sampling site location), *float* (2 levels indicate if floats were used on the gillnet), and *perp/para* (2 levels indicate if the net was set perpendicular or parallel to shore). A lognormal was select over a gamma model for the positive encounters by a delta AIC of 108.29. Covariates selected via AIC for both the lognormal binomial models included *year*, *site*, and *perp/para* (Table 35, Figure 30). The standardized index decreases from 1995-1998 and remains flat until through the early 2000's with three high years at the end of the time series (Figure 31).

The survey measured (standard length) every California scorpionfish encountered, totalling 1,130 fish. The majority of fish encountered were between 14 and 33 cm total length, with no strong trends or patterns in age classes during the time period (Figure ??)

Southern California Bight Regional Monitoring Project Trawl Survey

The southern California Coast Water Research Project SCCWRP consists of over 60 agencies in southern California that conduct monitoring of aquatic environments. One of the monitoring

966 programs in the Southern California Bight (SCB) is a trawl survey conducted every five years.
967 The pilot year of the survey was 1994. Data from each of the survey years (1994, 1998, 2003,
968 2008, and 2013) were provided by the SCCWRP (Shelly Moore).

969 In each of the five years of the study, sampling stations were chosen via a stratified random
970 sampling design (Bight '98 Steering Committee 1998). All participating agencies follow the
971 same protocols (net is towed 10 minutes at a speed of 1.0 m/sec) and use the same net
972 (semiballoon otter trawl). All fish and invertebrates are identified, counted, batch-weighed,
973 and measured (standard length to the nearest cm).

974 A series of data filters were applied to the dataset (Table ??). Only two scorpionfish were
975 encountered in hauls deeper than 450 m. Ninety-five percent of the data were retained for
976 hauls in shallower than 97 m, which was set as a filter. Stations in harbors (2/114 positive
977 hauls), north of Ventura (6/190 positive hauls) and the islands (16/117 positive hauls) were
978 excluded due to low encounters of California scorpionfish. The final dataset included 398
979 hauls, 129 of which encountered California scorpionfish. The unit of effort for this survey is
980 in kg per tow time (minutes).

981 Covariates considered for the delta-GLM model were *year* (5 levels), *area* (4 regions), and
982 *month* (3 levels; July-September). Sampling stations were assigned to one of four regions, 1)
983 Ventura to Long Beach, 2) Long Beach to Dana Point, 3) Dana Point to San Diego, and 4)
984 San Diego to the U.S./Mexico Border. A lognormal model was selected over a gamma model
985 for the positives by a delta AIC of 30. Depth (20-m depth bins) were considered, but none
986 of the levels were significant in a full lognorml or binomial model and was not considered
987 further. AIC selection for both the lognormal and binomial models selected all covariates
988 for the final model (Table 38). The Q-Q plot used to evaluate the goodness-of-fit of the
989 lognormal portion of the model is in Figures 32.

990 The standardized index of abundance indicates higher relative CPUE in 1994 and 2003, with
991 the other three years lower (Figure 33). The fact that the survey is conducted every five years
992 (4 years between the pilot and the 1998 survey), may preclude drawing any firm conclusions
993 on trends in abundance from this data.

994 The survey measured a total of 427 fish, with the last two years of the survey (2008 and
995 2013) only encountering 25 and 53 California scorpionfish, respectively.
996 However, the smallest fish observed in this survey were in 2013 (Figure 34).

997 *Generating Station Impingement Surveys*

998 Data from the southern California generating station surveys were provided by Eric Miller
999 (MBC Applied Environmental Sciences). The generating stations all draw in seawater
1000 through an intake system for once-through cooling water. There are five generating stations
1001 that conduct normal operation and heat treatment surveys with observations of California
1002 scorpionfish: Scattergood Generating Station (SGS), El Segundo Generating Station (ESGS),
1003 Redondo Beach Generating Station (RBGS), Huntington Beach Generating Station (HBGS),

1004 and San Onofre Generation Station (SONGS). Each generating station draws in water from
1005 different depths and distances from shore: SGS draws from 500 m offshore at 6 m depth,
1006 ESBS draws from 700 m offshore at 9.8 m depth, RBGS draws from 289 m offshore at 13.7 m
1007 depth, HBGS draws from 500 m offshore at 5 m depth, and SONGS has two intake systems
1008 960 m and 900 m offshore and at 9 m and 8 m depth, respectively (Miller et al. 2009).

1009 The two surveys conducted are normal operations surveys and heat treatment surveys. For
1010 normal operations surveys, the intake screens are rotated and cleaned to start the survey. All
1011 of the impinged fish are washed off the screen at this time and discarded. When the intake
1012 screens stop running, the survey begins. The generating station then operates as normal for
1013 24 hours, which includes operating and washing the screens as usual (typically every eight
1014 hours). The screens are then operated and washed again after a second 24 hours has elapsed.
1015 Any specimens washed off the screens during the 48 hour study period are retained. The total
1016 sample is processed to identify, count, weigh, measure the fish and macroinvertebrates. There
1017 is often no information on the water flow collected during the 48 hour period of the normal
1018 operations survey. Most fish enter the generating station and swim in the sedimentation
1019 basin until either getting exhausted or impinged. The SONGS generating station also has a
1020 fish elevator that releases a fraction of the fish back to the ocean.

1021 At each generating station, cooling water, i.e., seawater, is pumped into the generating station
1022 where it reaches a sedimentation basin. Water flow is uni-directional, and fish can reside
1023 in this area, but not escape. During a heat treatment, water in the sedimentation basin is
1024 heated to over 38 degrees Celsius, killing all fish and invertebrates, and impinging them on
1025 the travelling screens.

1026 The screens are operated and washed off per normal operating procedures right up until the
1027 heat treatment takes place. Therefore, only the fish remaining in the sedimentation basin
1028 and those impinged since the last screen rotation are counted in the heat treatment survey.
1029 The total flow between heat treatments has previously been used to standardize indices in
1030 previous reports. However, this is not representative of the flow relating to fish impinged
1031 during the heat treatment. The water flows vary widely among heat treatments, time of
1032 year (higher in summer when energy demands increase), and generating stations. Therefore,
1033 the generating station impingement surveys were not used to develop indices of abundance.
1034 However, length composition data from the impingement surveys were used.

1035 The length composition data from the impingement show a higher proportion of smaller (<10
1036 cm) fish since 2012 (Figure 36)

1037 *California Cooperative Oceanic Fisheries Investigations (CalCOFI) Survey* UCSD Scripps
1038 Institution of Oceanography, CDFG, and the National Marine Fisheries Service have carried
1039 out a plankton survey on a regular basis since 1951 (Moser et al. n.d.). Prior to 1965,
1040 *Scorpaena* samples were not speciated.

1041 California scorpionfish larvae encounters from CalCOFI surveys were provided by Noelle
1042 Bowlin (NMFS SWFSC). Only 16 positive bongo tows in the core area (lines 77-93) encountered
1043 California scorpionfish. The majority of the 335 positive bongo tows occurred in Mexico,

1044 south of Punta Eugenia Baja California and are likely a combination of California scorpionfish
1045 and other *Scorpaena* species. The California scorpionfish egg masses are encountered in
1046 the CalCOFI surveys, but because California scorpionfish is not a target species they are
1047 entered in the database as “unidentified eggs” (William Watson, NMFS SWFSC). An index
1048 of abundance was not developed for the CalCOFI data due to the small sample sizes.

1049 **2.2.4 Biological Parameters and Data**

biological-parameters-and-data

1050 Conversion factors California scorpionfish do not have a forked tail, therefore total length
1051 and fork length are equal. Love et al. (1987) provide conversion factors between standard
1052 length (SL) and total length (TL). $TL = 1.21SL + 1.02$ and $SL = 0.82TL - 0.69$.

1053 Standard and total lengths of 163 California scorpionfish were available from a halibut trawl
1054 survey in southern California (Steve Wertz, CDFW). The conversion from SL to TL from
1055 these data was estimated at $TL = 1.2225SL + 0.7773$.

1056 The conversion originating from the halibut trawl data was used in this assessment due to
1057 the fact that the original data from Love et al. (1987) are not available.

1058 The majority of available length composition data were measured to total length, except
1059 for three of the sanitation district trawl surveys, the Southern California Bight Regional
1060 Monitoring Program trawl survey, and the CSUN/VRG gillnet survey (gillnet survey).
1061 Maunder et al. (2005) converted all data to standard length due to clumping of data when
1062 length data are only available to the nearest centimeter. However, the same is true for the
1063 conversion from TL to SL when data are available to the nearest centimeter. All length data
1064 for this assessment are in TL. The Sanitation District of Orange county and the VRG gillnet
1065 study measured SL to the nearest mm.

1066 To avoid missing length bins (specifically 18, 23, 29 cm) in the conversion from SL to TL,
1067 0.5 was first subtracted from each SL and a random uniform number ($U[0, 1]$) was added to
1068 the SL measurement. All TL measurements were rounded to the nearest length centimeter
1069 length bin. A comparison of the length distributions

1070 **Length And Age Compositions**

1071 Include: Sample size information for length and age composition data by area, year, gear,
1072 market category, etc., including both the number of trips and fish sampled.

1073 Length compositions were provided from the following sources:

- 1074 • CDFW market category study (*commercial dead fish*, 1996-2003)
- 1075 • CALCOM (*commercial dead fish*, 2013-2016)
- 1076 • CDFW onboard observer (*recreational charter discards*, 2003-2016)
- 1077 • Ally onboard observer study (*recreational charter discards*, 1984-1989)

- California recreational sources combined (*recreational charter retained catch*)
 - CDFW and Ally onboard observer surveys (1984-1989)
 - Collins and Crooke onboard observer surveys (1975-1978)
 - MRFSS (1980-2003)
 - CRFS (2004-2014)
- California recreational sources combined (*private mode retained catch*)
 - MRFSS (1980-2003)
 - CRFS (2004-2016)
- Sanitation district trawl surveys (*research*, 1970-2016)
- CSUN/VRG gillnet survey (*research*, 1995-2008)
- Power plant impingement surveys (*research*, 1974-2016)
- Southern California Bight trawl survey (*research*, 1994, 1998, 2003, 2008, 2013)

The length composition of all fisheries aggregated across time by fleet is in Figure 37. Descriptions and details of the length composition data are in the above section for each fleet or survey.

Recreational: California MRFSS And CRFS Length Composition Data Individual fish lengths recorded by MRFSS (1980-2003) and CRFS (2004-2011) samplers were downloaded from the RecFIN website (www.recfi.org). CRFS data from 2012-2014 were obtained directly from CDFW.

Commercial: PacFIN

Age Structures Age data were provided from the NWFSC trawl survey from 2005-2016, and all of the otoliths collected from the survey were aged. Figures 38 and 39 provide examples of California scorpionfish otoliths from ... and ... The otoliths were read (including double-reads) by the Cooperative Ageing Project (CAP) in Newport, Oregon.

A total of 879 otoliths were read, and ranged from 0-29 years of age. Fewer than a 1% (8 fish) were aged 22 years or older, and only one age-0 fish was in the sample (Figure 40).

Sex-specific length-at-age was initially estimated external to the population dynamics models using the von Bertalanffy growth curve (Bertalanffy 1938), $L_i = L_\infty e^{(-k[t-t_0])}$, where L_i is the length (cm) at age i , t is age in years, k is rate of increase in growth, t_0 is the intercept, and L_∞ is the asymptotic length.

The external parameter estimates for females were $L_\infty = 31.613$, $k = 0.250$, $t_0 = -2.280$, and for males $L_\infty = 27.374$, $k = 0.233$, $t_0 = -2.092$ (Figure 41).

Aging Precision And Bias Uncertainty in ageing error was estimated using a collection of 200 California scorpionfish otoliths with two age reads (42).

Age-composition data used in the model were all from the NWFSC trawl survey and were from otoliths reads aged by the Cooperative Ageing Project (CAP) in Newport, Oregon. All of the otolith reads were from Age Reader A, and double reads were read by Age Reader B.

1115 Ageing error was estimated using publicly available software (Thorson et al. 2012).
1116 The software setting for bias and standard deviation were the same for both readers, unbiased
1117 and curvilinear increase in standard deviation with age, respectively (Figure 43). Two fish
1118 with estimated age greater than 21 (plus group age) were excluded from the ageing error
1119 estimation. The resulting estimate indicated a standard deviation in age readings increasing
1120 from 0.001 years to a standard deviation of 1.79 years at age 22.

1121 Weight-Length

1122 The weight-length relationship is based on the standard power function: $W = \alpha(L^\beta)$ where
1123 W is individual weight (kg), L is length (cm), and α and β are coefficients used as constants.

1124 Sex-specific weight-length relationships were estimated from the NWFSC trawl survey data.
1125 Length and weight data were available for 340 females and 530 males. The estimated
1126 parameters for females are $\alpha = 1.553983e^{-05}$ and $\beta = 3.057654$, and for males $\alpha = 1.9104e^{-05}$
1127 and $\beta = 2.980548$. Love et al. (1987) found males to be heavier at a given length than
1128 females, whereas the NWFSC data suggest the opposite (Figure 44).

1129 The original data from Love et al. (1987) are no longer available (Milton Love, personal
1130 communication, UC Santa Barbara) to re-examine the trends. The weight-length relationships
1131 estimated from the NWFSC survey are consistent with the sex-specific growth rates and are
1132 used in the assessment model.

1133 Maturity And Fecundity

1134 No new information on maturity and fecundity for California scorpionfish are available since
1135 the publication of the 2005 stock assessment. Few California scorpionfish are mature at age 1,
1136 but over 50% are mature at age 2 and most are mature at age 3 (Love et al. 1987).

1137 Biological data from California scorpionfish collected from a bi-monthly California halibut
1138 cross-shelf survey were provided by Steve Wertz at CDFW. The data includes length, sex,
1139 body weight, and gonad weight from 156 fish, 23 of which were immature.

1140 The proportion mature at length from the survey does not give a good indication of the size
1141 at maturity (Table 40). The gear used in the survey...

1142 The assessment model assumes

1143 **Natural Mortality** Hamel (2015) developed a method for combining meta-analytic ap-
1144 proaches to relating the natural mortality rate M to other life-history parameters such as
1145 longevity, size, growth rate and reproductive effort, to provide a prior on M . In that same
1146 issue of ICESJMS, Then et al. (2015), provided an updated data set of estimates of M and

related life history parameters across a large number of fish species, from which to develop an M estimator for fish species in general. They concluded by recommending M estimates be based on maximum age alone, based on an updated Hoenig non-linear least squares (nls) estimator $M = 4.899 * A_{max}^{-0.916}$. The approach of basing M priors on maximum age alone was one that was already being used for west coast rockfish assessments. However, in fitting the alternative model forms relating $-0.916M$ to A_{max} , Then et al. (2015) did not consistently apply their transformation. In particular, in real space, one would expect substantial heteroscedasticity in both the observation and process error associated with the observed relationship of M to A_{max} . Therefore, it would be reasonable to fit all models under a log transformation. This was not done. Reevaluating the data used in Then et al. (2015) by fitting the one-parameter A_{max} model under a log-log transformation (such that the slope is forced to be -1 in the transformed space (as in Hamel (2015)), the point estimate for M is:

$$M = \frac{5.4}{A_{max}} \quad (1)$$

The above is also the median of the prior. The prior is defined as a lognormal with mean $\ln \frac{5.4}{A_{max}}$ and SE = 0.4384343. Using a maximum age of 21 the point estimate and median of the prior is 0.2545, which is used as a prior for females in the assessment model.

Sex ratios

The sex ratio from the aged California scorpionfish for this assessment were approximately 60% males and 40% females. These fish all came from the NWFSC trawl survey from 2005-2016.

[previous-assessments](#)

2.3.2 2005 Assessment Recommendations

[assessment-recommendations](#)

Include: Response to STAR panel recommendations from the most recent previous assessment.

Recommendation 1: The sanitation surveys conducted to track the impact of sewage outfall provided a fishery independent index of abundance for

1173 scorpionfish. This data source should be more fully explored for other
1174 near-shore species of recreational or commercial interest. Methods should
1175 be developed to produce a more statistically rigorous index from the
1176 separate surveys.

1177

1178 STAT response: Data from all sanitation districts in southern California were obtained
1179 for this assessment. All of the data were pooled across surveys to develop one index of
1180 abundance using the delta-GLM method

1181 **Recommendation 2: An age, growth and maturity study for scorpionfish is**
1182 **needed. Although there has been previous research on scorpionfish age and**
1183 **growth, the available information is not appropriate for stock assessment**
1184 **modeling.**

1185

1186 STAT response: Age data are available from the NWFSC trawl survey from 2005-2016.
1187 There have been no additional studies on growth or maturity for California scorpionfish
1188 since the 2005 assessment.

1189 **Recommendation 3: Location information for the historic groundfish data of all**
1190 **species is currently available, in hard copy form only, from the California**
1191 **Department of Fish and Game. Putting this information into electronic**
1192 **format would greatly improve the ability to assign catches of all species to**
1193 **specific stocks on a trip-by-trip basis.**

1194

1195 STAT response: The location-specific catches referred to above have been key-punched
1196 and are available in electronic form from the SWFSC, Santa Cruz.

1197 **Recommendation 4: The SS2 model should be modified to allow for projections**
1198 **of user-specified recruitment at user defined values. It would be most**
1199 **helpful if the default harvest policies were then recalculated automatically**
1200 **for these user-specified recruitments.**

1201

1202 STAT response: The status of this within Stock Synthesis is unknown.

1203 2.4 Model Description

model-description

1204 2.4.1 Transition To The Current Stock Assessment

transition-to-the-current-stock-assessment

1205 Include: Complete description of any new modeling approaches

1206 Below, we describe the most important changes made since the last full assessment and
1207 explain rationale for each change.:

- 1208 1. Change No. 1. *Rationale*: blah blah blah.
1209 2. Change No. 2. *Rationale*: blah blah blah.
1210 3. Change No. 3. *Rationale*: Continue list as needed.

1211 **2.4.2 Definition of Fleets and Areas**

definition-of-fleets-and-areas

1212 We generated data sources for each of the models. Fleets by model include:

1213 **Model Region 1 or remove this line if only one model**

1214 *Commercial*: The commercial fleets include...

1215 *Recreational*: The recreational fleets include...

1216 *Research*: Research derived-data include...

1217 **2.4.3 Summary of Data for Fleets and Areas**

summary-of-data-for-fleets-and-areas

1218 **2.4.4 Modeling Software**

modeling-software

1219 The STAT team used Stock Synthesis 3 version 3.30.0.4 by Dr. Richard Methot at the NWFSC.
1220 This most recent version was used, since it included improvements and corrections to older
1221 versions. The r4SS package (GitHub release number v1.27.0) was used to post-processing
1222 output data from Stock Synthesis.

1223 **2.4.5 Data Weighting**

data-weighting

1224 Citation for Francis method (Francis 2011)
1225 Citation for Ianelli-McAllister harmonic mean method (McAllister and Ianelli 1997)

1226 **2.4.6 Priors**

priors

1227 Citation for Hamel prior on natural mortality (Hamel 2015)

1228 **2.4.7 General Model Specifications**

general-model-specifications

1229 Model data, control, starter, and forecast files can be found in Appendices A-D.

1230 **2.4.8 Estimated And Fixed Parameters**

estimated-and-fixed-parameters

1231 A full list of all estimated and fixed parameters is provided in Tables.... Estimated and fixed
1232 parameters tables currently read in from .csv file, EXAMPLE: Table ??

1233 **2.5 Model Selection and Evaluation**

model-selection-and-evaluation

1234 **2.5.1 Key Assumptions and Structural Choices**

key-assumptions-and-structural-choices

1235 Include: Evidence of search for balance between model realism and parsimony.

1236 Comparison of key model assumptions, include comparisons based on nested models (e.g.,
1237 asymptotic vs. domed selectivities, constant vs. time-varying selectivities).

1238 **2.5.2 Alternate Models Considered**

alternate-models-considered

1239 Include: Summary of alternate model configurations that were tried but rejected.

1240 **2.5.3 Convergence**

convergence

1241 Include: Randomization run results or other evidence of search for global best estimates.

1242 Convergence testing through use of dispersed starting values often requires extreme values to
1243 actually explore new areas of the multivariate likelihood surface. Jitter is a SS option that
1244 generates random starting values from a normal distribution logically transformed into
1245 each parameter's range (Methot 2015). Table 43 shows the results of running 100 jitters for
1246 each pre-STAR base model....

1247 **2.6 Response To The Current STAR Panel Requests**

response-to-the-current-star-panel-requests

1248 **Request No. 1: Add after STAR panel.**

1249

1250 **Rationale:** Add after STAR panel.
1251 **STAT Response:** Add after STAR panel.

1252 **Request No. 2: Add after STAR panel.**

1253
1254 **Rationale:** Add after STAR panel.
1255 **STAT Response:** Add after STAR panel.

1256 **Request No. 3: Add after STAR panel.**

1257
1258 **Rationale:** Add after STAR panel.
1259 **STAT Response:** Add after STAR panel.

1260 **Request No. 4: Example of a request that may have a list:**

1261
1262 • **Item No. 1**
1263 • **Item No. 2**
1264 • **Item No. 3, etc.**

1265 **Rationale:** Add after STAR panel.
1266 **STAT Response:** Continue requests as needed.

1267 **2.7 Model 1**

model-1

1268 **2.7.1 Model 1 Base Case Results**

model-1-base-case-results

1269 Table ??

1270 **2.7.2 Model 1 Uncertainty and Sensitivity Analyses**

model-1-uncertainty-and-sensitivity-analyses

1271 Table 44

1272 **2.7.3 Model 1 Retrospective Analysis**

model-1-retrospective-analysis

1273 **2.7.4 Model 1 Likelihood Profiles**

model-1-likelihood-profiles

1274 **2.7.5 Model 1 Harvest Control Rules (CPS only)**

model-1-harvest-control-rules-cps-only

1275 **2.7.6 Model 1 Reference Points (groundfish only)**

model-1-reference-points-groundfish-only

1276 Intro sentence or two....(Table 45).

1277 Equilibrium yield at the proxy F_{MSY} harvest rate corresponding to shows the full suite of
1278 estimated reference points for the northern area model and Figure j shows the equilibrium
1279 yield curve.

1280 **3 Harvest Projections and Decision Tables**

harvest-projections-and-decision-tables

1281 Table f

1282 **Model 1 Projections and Decision Table (groundfish only) (Table 46**

1283 Table h

1284 **Model 2 Projections and Decision Table (groundfish only)**

1285 **Model 3 Projections and Decision Table (groundfish only)**

1286 **4 Regional Management Considerations**

regional-management-considerations

- 1287 1. For stocks where current practice is to allocate harvests by management area, a
1288 recommended method of allocating harvests based on the distribution of biomass should
1289 be provided. The MT advisor should be consulted on the appropriate management
1290 areas for each stock.
- 1291 2. Discuss whether a regional management approach makes sense for the species from a
1292 biological perspective.
- 1293 3. If there are insufficient data to analyze a regional management approach, what are the
1294 research and data needs to answer this question?

₁₂₉₅ **5 Research Needs**

research-needs

- ₁₂₉₆ 1. Research need No. 1
- ₁₂₉₇ 2. Research need No. 2
- ₁₂₉₈ 3. Research need No. 3
- ₁₂₉₉ 4. etc.

₁₃₀₀ **6 Acknowledgments**

acknowledgments

₁₃₀₁ Include: STAR panel members and affiliations as well as names and affiliations of persons
₁₃₀₂ who contributed data, advice or information but were not part of the assessment team. Not
₁₃₀₃ required in draft assessment undergoing review. We thank Kevin Lee for the use of the cover
₁₃₀₄ photo for this document.

Table 6: Recreational private mode dockside data sample sizes at each data filtering step. The bold value indicates the final sample size used for delta-GLM analysis.

tab:Fleet4_RecPR_dockside_filter			
Filter	Criteria	Sample size (no. positive trips)	Sample size (no. of trips)
Entire dataset			108,171
General data filters	CRFS-PR1 survey only, Southern California only (sub_reg = 1), Hook and line gear only (geara = 'H'), Ocean only (Area_X = 1 or 2)	3,802	43,956
Region	Remove trips from Santa Barbara	3,757	42,956
Year	Remove 2004-2005; fishery closed majority of year	3,094	33,770
Closed fishery	Remove remaining trips when fishery closed	3,056	32,236
Rare and co-occurring species	Remove trips with yellowfin tuna and dolphinfish and species present in $\geq 1\%$ of all trips and in at least 5 years of data	3,056	30,033
Stephens-MacCall	Retain all positive trips, plus "False Positives" (trips predicted to be in California scorpionfish habitat, but with no California scorpionfish retained)	3,056	8,590

Table 10: Recreational CPFV logbook sample sizes at each data filtering step. The bold value indicates the final sample size used for delta-GLM analysis.

Filter	Criteria	tab:Fleet5_RecPC_CPFVlogbook_filter	Sample size (no. of trips)
All CA data	No filter		1,164,662
Gear	Remove trips reported as diving, mooching or trolling		959,740
Effort or missing data	Remove trips with missing effort or species information		930,233
Year	Remove 2017, remaining years 1980-2016		929,781
Region	Remove trips north of Pt. Conception and in Mexico		568,222
Fish encountered	Remove trips reporting number of retained fish greater than in the 99% quantile (>325 fish)		564,433
Target species	Remove trips targeting sharks, striped bass, sturgeon, tun, misc. bay, and potluck		558,872
Single-species trips	Filter trips reporting catches of only species and that one species in <100 trips		558,833
Offshore trips	Remove trips catching yellowtail, tunas, and dolphinfish that were not designated as offshore trips		475,492
Vessel	Remove trips by vessels that had fewer than 10 trips catching scorpionfish		466,023
Anglers	Remove trips with number of anglers < the 1% and > the 99% quantile (retain 5-75 anglers)		452,938
Depth	Remove trips in blocks with a minimum depth of >140m		443,929
Scorpionfish targets	Blocks with at least 100 scorpionfish trips		433,248
Sample size	Blocks with at least 500 trips		432,868

Table 13: Recreational CPFV dockside sample sizes at each data filtering step. The bold value indicates the final sample size used for delta-GLM analysis.

Filter	Criteria	tab:Fleet5_RecPC_dockside_filter
		Sample size (no. of trips)
All southern CA data	No filter	6295
Offshore trips	Remove trips with catch of yellowfin tuna, bluefin tuna, albacore, chinook salmon, coho salmon, bigeye tuna and skipjack	6180
Species	Remove trips with catch of Pacific bonito	4718
County	Remove trips from Santa Barbara County	4338
Effort	Remove trips with lower and upper 2.5% of angler hours (± 2 or ± 109.5).	4117
Second species filter	Remove trips with catch of yellowtail (<i>Seriola lalandi</i>); remove chub/Pacific mackerel and barracuda as predictors	3968
Stephens-MacCall	Retained all trips with California scorpionfish as well as trips identified as false negatives and probability of encounter of 0.10	3176
Year	Removed trips from 1989 due to anomalous results and low sample size	3,099

Table 14: AIC values for each model in the recreational CPFV logbook sample index, including all positive trips and false positive trips selected with a Stephens-MacCall filter threshold encounter probability of 0.1.

Table 42: Summary of the biomass/abundance time series used in the stock assessment.

Fleet	Years	Name	Fishery ind.	Filtering	Method	<small>\tab{Index_summary}</small>
4	2004-2016	Recreational PR dockside CPUE	No	trip, area, regulations, Stephens-MacCall	delta-GLM (bin-lognormal)	SSC
5	1980-2016	CPFV logbook CPUE	No	trip, gear, effort, species, depth, sample size	negative binomial	SSC
6	2002-2016	Onboard observer discard catch CPUE	No	habitat ,regulations, effort, boats	delta-GLM (bin-lognormal)	SSC
7	1970-2016	Sanitation district CPUE	Yes	sample size, depth, tow times	delta-GLM (bin-lognormal)	SSC
8	2003-2016	NWFSC trawl survey CPUE	Yes	depth, area	delta-GLM (bin-lognormal)	SSC
9	1995-2008	CSUN/VRG Gillnet survey CPUE	Yes	gear, site, month	delta-GLM (bin-lognormal)	SSC
11	1994; 1998; 2003; 2008; 2013	Southern California Bight trawl survey CPUE	Yes	depth, area	delta-GLM (bin-lognormal)	SSC
12	2002-2016	Onboard observer retained catch CPUE	No	habitat, regulations, effort, boats	delta-GLM (bin-lognormal)	SSC

Table 43: Results from 100 jitters from each of the three models.

Status	Model.1	Model.2	Model.3	tab:jitter
Returned to base case	-	-	-	
Found local minimum	-	-	-	
Found better solution	-	-	-	
Error in likelihood	-	-	-	
Total	100	100	100	

Table 45: Time-series of population estimates from the base-case model.
